

Chemical & Metallurgical Engineering

A Weekly Technical Newspaper,
Being the Incorporation of
Electrochemical and Metallurgical Industry
and Iron and Steel Magazine

Volume XXIII

From July 1 to December 31, 1920

NEW YORK
McGraw-Hill Company, Inc.

INDEX TO VOLUME XXIII

GENERAL ALPHABETICAL INDEX

PAGES			
July 7	1 to 44	ALUMINUM <i>Continued</i> :	
July 14	45 to 88	— Japanese trade	718
July 21	89 to 132	— Need for work on	1202
July 28	133 to 176	— Nickel-tungsten and its alloys	119
Aug. 4	177 to 220	— Guillet and Gasnier (S.)	119
Aug. 11	221 to 264	— Solder for	1240
Aug. 18	265 to 312	— Welding steels (B. P.)	1240
Aug. 25	313 to 360	Aluminum: Copper Alloys	
Sept. 1	361 to 408	— Some theoretical principles of alloy-	
Sept. 8	409 to 501	ing, Anderson	*319
Sept. 15	502 to 552	— Diffusion of solid copper in liquid	
Sept. 22	553 to 600	aluminum, Anderson	*575
Sept. 29	601 to 648	— Mfr. of rich copper: aluminum alloys	
Oct. 6	649 to 712	or hardeners, Anderson	*617
Oct. 13	713 to 760	— Foundry methods for light aluminum:	
Oct. 20	761 to 808	copper alloys, Anderson	735
Oct. 27	809 to 856	— Experiments in mfr. of No. 12 alloy,	
Nov. 3	857 to 904	Anderson	*883
Nov. 10	905 to 952	— Containing titanium, Stay	988
Nov. 17	953 to 1000	Aluminum: lithium alloys (B. P.)	1228
Nov. 24	1001 to 1048	Aluminum chloride, Mfr. of, Frary (P.)	892
Dec. 1	1049 to 1096	Aluminum nitride, Shoeld (P.)	306
Dec. 8	1097 to 1144	AMERICAN CERAMIC SOCIETY:	
Dec. 15	1145 to 1192	— Fall meeting, Chicago:	
Dec. 22	1193 to 1240	Program	255
Dec. 29	1241 to 1280	— Ceramic Day at Chemical Exposition:	300
		Announcement	501
		Report	675
		— Spring meeting, 1921, Columbus:	
		Announcement	901 1272
		AMERICAN CHEMICAL SOCIETY:	
		— Fall meeting, Chicago:	
		Committees	37
		— Preliminary program	100
		Special train service	351
		Program	*372
		Report	*556
		— Leather Section report	613
		Fertilizer Division report	693
		Rubber Division report	738
		— Symposium	792
		Industrial Excursions	*835
		Nominations for president	818
		American Coke & Chemical Co. St. Louis	992
		plant	
		AMERICAN ELECTROCHEMICAL SOCIETY:	
		— Fall meeting, Cleveland:	
		Preliminary announcement	39
		Program	590
		Report	*719
		— No official action on duty free im-	
		portations	1131
		— Spring meeting, Announcement	1131
		American Electroplaters' Society:	
		Rochester meeting, Report	125
		AMERICAN ENGINEERING COUNCIL:	
		— First meeting, Washington:	
		Announcement	593
		Report	*1052
		AMERICAN FOUNDRYMEN'S ASSOCIATION:	
		— Columbus meeting:	
		Preliminary note on exhibits	126
		Tentative program	594
		Report	705
		AMERICAN INSTITUTE OF CHEMICAL	
		ENGINEERS:	
		— Canadian meeting, Report	*19
		Chemical exposition meeting, Report	*664
		Special joint meeting, Government	817
		— New Orleans meeting:	
		Program	1038
		Report	*1188
		American Institute of Fertilizer Chemists	401
		AMERICAN INSTITUTE OF MINING AND	
		METALLURGICAL ENGINEERS:	
		— Fall meeting, Lake Superior:	
		Report	365
		— New York meeting, Report	822
		AMERICAN PETROLEUM INSTITUTE:	
		— Washington meeting:	
		Announcement	848
		Report	108
		— To establish research department	1272
		AMERICAN SOCIETY OF MECHANICAL	
		ENGINEERS:	
		— Materials Handling Section	800
		— New York meeting:	
		Program	1087
		AMERICAN SOCIETY FOR STEEL TREATERS:	
		— Fall meeting, Philadelphia:	
		Program	400
		Report	565, 633
		American Steel & Wire Co., A. Cer. S.	371
		— visit	
		American Steel Treating Society (see	
		American Society for Steel Treating)	
		American Tar Products Co. sold	580
		American Window Glass Co. plant im-	
		provements	896
		American Writing Paper Co. service bureau	1272
		Amias, Aromatic, Decolorizing (B. P.)	300
		Aminophenol derivatives, Kolshorn	1036
		(B. P.)	
		AMMONIA:	
		— Action of steam and gases on yields of	
		ammonia from carbonization of oil	
		shales and coal, Franks	1119
		— Anhydrous, Shortage of	124
		— Anhydrous, Factors contributing to	
		shortage of	212
		— Column stills for, Thau	*1203
		Synthetic:	
		— Analysis of (B. P.)	*790
		— Apparatus for, L'Air Liquide	
		(B. P.)	*539
		— Apparatus for (B. P.)	209
		— Catalysts for, Duparc and Ufer	
		(B. P.)	77
		— Claude process, Claude (S.)	395
		— Italian process	945
		— Nitrogen: hydrogen mixtures for	
		lamps (B. P.)	*637
		— Use in ammonia-soda process, B.	
		A. S. F. (B. P.)	707
		Ammonium perchlorate, Mfr. of, Given,	
		McQuaid and Long (P.)	208
		AMMONIUM SULPHATE:	
		— English improvements in mfr. of	800
		Mfr. of (B. P.)	1132
		— Neutral (B. P.)	350
		— Neutral (B. P.)	397, 398
		— Recovery by direct process	*323
		— Recovery from coke oven gas, Torrey	
		(P.)	708
		Anacomb Copper Mining Co.:	
		Report	136
		— To mfr. fertilizer	630
		Annual products industry, Future of	
		Richardson	*481
		Anthracene, Purification from carbazol	
		(B. P.)	847
		Anthraquinone by catalytic oxidation	
		Weiss and Downs (P.)	1131
		Anthraquinone, Purification of (B. P.)	752
		Anthraquinone derivatives, Cassella	
		(B. P.)	1229
		Antimony:	
		— Refining with chlorine, Bonnard	
		(B. P.)	1037
		— Revised atomic weight, Willard	
		(N.)	562
		Apothosis as local anesthetic	1106
		Apparatus standardization, Industrial	1233
		Apparatus standards and reagent packages	801
		Arco Co. varnish fume recovery plant	*771
		Argentina, Paper pulp industry in	1124
		Armor, Analysis of samples of ancient	975
		Army General Staff may be ousted	913
		Arsenic:	
		— Effect in steel, McKinney	294
		— For mfr. of, Jones	*957
		— White (see Arsenic Trioxide)	
		Arsenic Compounds, Organic:	
		— Mfr. of, Job and Guinet (B. P.)	941
		— Mfr. of, Pope (B. P.)	751
		— Mfr. of, Mountgat (B. P.)	*750
		Arsenic trioxide industry in Japan	1007
		Asbestos:	
		— Can be fine spun	101
		— Increased demand for high grade	231
		Asphalt, Dry distillation of Matita asphalt-	
		um, Nicolsen-Olin	631
		Association of Iron and Steel Electrical	
		Engineers:	
		— New York meeting, Program	541
		Association of Official Agricultural Chemists:	
		— Report of Washington meeting	1088
		Atmospheric impurities, Determination of	
		Monnett	*1117, 11
		Atomic and molecular structure, Models of	
		Poster	*690
		Australia, Pigment deposits in	289
		Automobile exhaust gases, Composition	
		of, Fieldner (N.)	942
		B	
		Babbitt (see Bearing metal)	
		Bach Brick Co., A. Cer. S. visit	369
		Bacon cracking process	911
		Bacteriological work, Sugars in, Etal	564
		(N.)	168
		Bakelite used for airplane propellers	
		Ball-bearing races, Electric heat treat-	
		ment of	*118
		Baltimore Engineers' Club formed	1087
		Barber Asphalt Paving Co. plant destroyed	
		by fire	702
		Barium carbonate, Mfr. Langwell (B. P.)	300
		Barium chloride, Small-scale mfr. of	
		Munroe	188
		Barium peroxide, Mfr. of, Fleck (P.)	847
		Bating, Mechanism of, Wilson (N.)	944
		Bauxite industry active	
		Bearing Metal:	
		— Compression and hardness of white	992
		metal	472
		— Bearing alloys	
		Beet sugar (see Sugar)	
		BELGIUM:	
		— Chemical company developments	878
		— Metallurgical industry in (S.)	*747

*Illustrated; (P.), (B. P.)—United States and British patents respectively; (S.)—Synopsis; (N.)—Papers read at society meetings but not printed in full.

BELGIUM—Continued:		
—Soap industry. Condition of.	746	
—Status of artificial silk industry.	696	
Bolting:		
—Lather. Research and production of.	628	
—Substitutes for leather used in Germany. Heise.	936	
Benzene:		
—Column stills for. Thau.	1203	
—Determination of, in motor fuels.		
—McCormack, (N.)	561	
—Process and equipment for refining benzene hydrocarbons. Thau.	1065	
—Retains from beet sugar molasses.	423	
—Bismetal. Todesco, (P.)	847	
BIBLIOGRAPHIES:		
—Arsenic	959	
—Boiling points of sodium chloride solutions.	574	
—Diatomaceous earth. Goodwin.	1156	
—Gasoline cracking processes. Patents on.	911	
—Glues and gelatines.	201	
—Biology. Chemistry in. Lowenhart, (N.)	558	
—Birmingham Glass Mfg. Co.	353	
—Bishop, Joseph. Platinum worker. Hart.	1191	
—Bismuth oxide. Mfr. of. Darling, (P.)	802	
—Bituminous acid-proof coatings for concrete surfaces.	287	
—Bituminous sand deposits. Athabasca.	1245	
—Boiler. Mercury. Emmet, (N.)	559	
—Boiler installation. French producer fastened. Bartlett.	1033	
—Boiler plant efficiencies in English chemical works. Brownlie.	939	
—Boiling points of salt solutions. Badger and Baker.	569	
—Book reviews.	169, 213, 257, 307, 355, 402, 544, 593, 641, 706, 945, 993, 1012, 1137, 1180.	1273
BOOK REVIEWS:		
—Alderson, Victor C. The Oil-Shale Industry.	593	
—Allen. Handbook of Ore Dressing.	910	
—Baker. New Industrial Unrest.	1139	
—Black and Conant. Practical Chemistry.	307	
—Coughlin. The Modern Electrolater.	1180	
—Falk. Chemical Reactions.	1042	
—Friend. A Text Book of Inorganic Chemistry.	705	
—Hale. The Manufacture of Chemicals by Electrolysis.	705	
—Hamilton. Manual of Cyanidation.	945	
—Hatchek. Laboratory Manual of Elementary Colloid Chemistry.	918	
—Logan. Kaolin of Indiana.	1138	
—Lyons. Practical Standardization by Chemical Assay of Organic Drugs and Galenicals.	705	
—Mees. The Organization of Industrial Scientific Research.	641	
—Ober and James. Iron and Steel.	355

—Soddy. Science and Life.	545	
—Sprag. Non-Technical Chats on Iron and Steel and Their Application to Modern Industry.	213	
—Tud and Metcalf. Personnel Administration: Its Principles and Practice.	612	
—Thomas. Surveying.	545	
—Weed. The Mines Handbook.	257	
—Wells and Fogg. The Manufacture of Sulphuric Acid in the United States.	1139	
—White. Gas and Fuel Analysis.	1138	
—White and Wick. Water Powers of British Columbia.	402	
—Williams. What's on the Worker's Mind?	1137	
—Borax in fertilizers. Breckenridge, (N.)	693	
—Borneol. Mfr. of. (B. P.)	847	
—Bose. Who is your?	832	
—Boston University. Havana branch.	39	
—Brain. Chemistry of. West.	145	
BRASS:		
—Brass foundry fluxes. Hill, Thomas and Vics, (N.)	767	
—Electric furnace mfr. Status of.	983	
—Electrodeposition from cyanide solutions. Ferguson and Sturdevant, (N.)	723	
—Reclaiming brass foundry refuse. Wolf and Alderson, (N.)	767	
—Brazil. Sugar industry in.	887	
—Bridge River Power Co. Ltd.	79	
—Bridgeport Chapter, A. S. M. E.		
—October meeting. Lead.	942	
—Brine. Purification for electrolysis. Wheeler, (P.)	301	
BRIQUETTING:		
—Fine ores. Hills and Wheeler, (B. P.)	35	
—Low-grade coal in Winnipeg.	241	
—Oklahoma coal. Davis.	101	
—Smokeless fuel briquets. Curtis.	499	
—Brinell test. Use of etched balls in.	639	
—British Chemical Industry.	33, 181, 364, 652, 860.	1106
British Columbia:		
—To develop iron deposits.	820	
—Coast Range Steel, Ltd., incorporated.	1090	
—Turpentine and rosin industry in.	338	
British Cotton-Growing Research Association report		641
Bromates. Mfr. of. Jones, (P.)		396
Bureau of Chemistry:		806
—Development work in application of research.	351	
—Work on phthalic anhydride and furfural.	703	
Bureau of Internal Revenue, Division of Technology subdivided		840
BUREAU OF MINES:		
—Ceramic engineer sought for.	1135	
—Chemical work strengthened.	127	
—Co-operative work to be pushed.	943	
—Dr. Cottrell may withhold resignation.	898	
—W. R. Crane sent to Tuscaloosa.	810	
—Division of non-ferrous metallurgy.	351	
—Engineer needed for non-metals work.	1040	
—Golden station forced to move.	4	
—Golden station moves to Reno.	120	
—Industrial films.	895	
—Low-temperature research laboratory.	210	
—Mississippi Valley Experiment Station at Rolla, Mo.	644, 641, 891	
—Non-metal work at Tuscaloosa.	800	
—Seeking site for non-metallic station.	165	
—Final plan delayed.	212	
—To assist in superpower survey.	109	
BUREAU OF STANDARDS:		
—Appropriations asked.	1185	
—Conference with color committee of Cottonseed Oil Chemists.	500	
—Co-operation with American Committee on Electrolysis.	304	
—Gas appliance investigations.	528	
—Losses many scientists.	709	
—Organization and work of.	984	
—Personnel changes.	1233	
—Burma. Market for American dyes in.	12	
—Burton cracking process.	908	
—Butter. Chemistry of churning.	351	
—Butter substitutes: (see Margarine).		
—Butterworth Judson Corp. plant burned.	705	
C		
Cadmium. Electrolytic production. Hay		1257
Cadmium production in 1910. (S.)		252
Calandria vacuum pan. Foundry work on.		814
Stanley		1132
Calcium aluminate. (B. P.)		1040
Calcium arsenate conference.		1183
Calcium cyanamide: (see Cyanamide.)		
California Section, A. C. S.		
Annual meeting		1183
Camp:—		
Industry in Froehow.		844
From isoborneol. Andrian, (P.)		540
Japan discontinues allotments for export of crude.		528
CANADA:		
Baking-powder and flavoring extract industry in 1918.		601
Canada and the chemists. Price.		672
Greva.		332
Conserving pulpwood resources.		897
Denatured alcohol regulations amended.		641
Paint industry.		326, 720
Paper and pulp exports.		1080
Petroleum and natural gas rulings.		1056
Pulpwood laws and regulations.		1171
Starch and glucose industry.		371, 401
Sugar industry in.		153
Wood-distillation industry of.		1000
Canada Copper Corp. reorganized.		35
Canadian Electro Leather Industries.		501
Carbazol. Mfr. of. (B. P.)		729
Carbocool plant at Clinchfield.		785
Carbon black:		
Channel process for mfr. of. Neal.		340
Disk, plate, and cylinder processes.		817
Neal.		769
Carbon dioxide. Mfr. of. Tomlinson, (S.)		
Carbon disulphide. Mfr. of. Dow and Strosacker, (P.)		754
Carborundum as a refractory. Hartman, (N.)		1000
Carnegie Institute of Technology:		
Additions to faculty.		1181
Coal-mining laboratory.		
Catalytic processes. Mechanism of. Taylor, (N.)		
Caustic soda: (see Sodium hydroxide.)		
Caustic liquors. Graphic calculation of neutralization with CO₂. Dittmer.		1170
Cell. Standard. New type of. Rodman and Spooner, (N.)		722
CELLULOSE:		
Carbohydrates from. Wohl, (B. P.)		1133
Cellulose content of compound celluloses. Kahlenberg, (N.)		563
Cellulose mucilage. Minor, (N.)		126
Cellulose section. A. C. S. considered.		563
Cellulose symposium. A. C. S.		
Chemistry of cellulose and its compounds from colloidal standpoint.		861
Esselen.		563
Comparison of wood and cotton cellulose. Mahood, (N.)		563
Constitution of. Hibbert.		563
CELLULOSE ACETATE:		
Compositions. British Cellulose. (B. P.)		1036
In artificial wool.		896
Mfr. of. A. G. F. A. (B. P.)		1036
Mfr. of. Badische. (B. P.)		989, 990
Mfr. of. Deschens.		533
Mfr. of. S. C. U. R. (B. P.)		1132
Mfr. of. Zdanowich, (P.)		540
Molding. (B. P.)		1228
Properties and industrial use of.		581
Deschens		
Cellulose esters. Mfr. of. Lallenfeld, (B. P.)		1270
Cellulose esters. Solution in furfural. Bonwit, (B. P.)		35
Centrifugal process for recovering oil from soapstock. Ayres.		1025
CERAMICS:		
Bonding clays for crucibles.		307
Ceramic clay at chemical exposition.		875
Composition of kiln gases and effect on terra cotta glasses. Ortmann, (S.)		251
Glasses. Study of hardness of.		920
Porcelain without silica base. Dautzen, (P.)		301
Post-war status of ceramic industries.		629
Reininger.		692
Pottery industry in 1910.		365
Properties of stoneware clays.		384
Schuericht, (S.)		385
Cerium alloys. Experiments to be made on Ceylon rubber industry.		288
Ceylon. Hydro-electric development in.		377
Chain driving. A study of.		511
Charcoal. Activated. Recovery of industrial vapors with. Barneby, (N.)		107
Charcoal. C. W. S. work on special.		
CHARTS:		
Alignment:		
Fuel waste.		650
Flow of steam in pipe lines.		1172
Heat wasted due to excess air.		659
Neutralization of caustic liquors with CO₂.		1170
Chemical and physical constants. Need for reliable. Richards.		447
Comment. Liddell.		716
Chemical Engineer:		
Duties of. Wesson, (N.)		664
Functions and training of. Moulton, (N.)		501
Functions and training. West.		335
Functions of. Wesson, (N.)		489
Functions of. Withrow, (N.)		1100
CHEMICAL ENGINEERING:		
Disabled ex-service men take up.		801
Institutions giving courses in.		542
M. I. T. School of Chemical Engineering Practice. Haslam.		605
Studies published by British Ministry of Munitions.		652
CHEMICAL INDUSTRY:		
British: (see England, British chemical industry.)		
European. Dr. Parsons on.		303
European chemical plants. Conditions of. Norris, (N.)		1030
Expansion in U. S. since 1914.		592
Exposition of: (see National Exposition of Chemical Industries.)		
French: (see France. Notes on French industries.)		
German chemical industry. Conditions in.		889
Chemical market.		41, 83, 124, 171, 215, 259, 308, 356, 403, 546, 595, 613, 707, 755, 804, 852, 890, 948, 991, 1043, 1091, 1130, 1180, 1234.
Chemical profession—Its opportunity and responsibility. McBride.		502
Comment. Blauvelt.		1004
Chemical warfare display interests public.		512
Chemical Warfare Post meeting.		703
CHEMICAL WARFARE SERVICE:		
Notes on.		303
Officers' Reserve Corps.		399
Patent policy.		541
Surplus gas policy.		541
Consulting staff.		512
Needs more officers.		544
Needs \$10,000,000 appropriation.		544
Chemical advisory committee named.		638
Officers appointed.		704
Ethylene recovery to be studied.		701
Co-operative agreement with chemical industries.		705
Chemists submit ideas to.		848
Remuneration for consulting chemists.		810
Quarters sought for civilians at Edgewood.		993
Quarters for civilians refused.		840
New examination for commissions.		896
Officers' Reserve Corps.		897
Failure to appoint officers.		1087
Looking for chief chemist for Edgewood Arsenal.		942
Consulting chemists named.		1040
A. C. S. advisory subcommittee chairmen named.		1185
Approved.		1131
Commissions granted.		1135
Annual report by General Fries.		1184
Appropriation asked.		1041
Chemical Warfare Service Association.		1089
Chemicals. Handling. More care needed in.		1041
Chemicals. Tonnage carried by railroads.		706, 1089
Chemist and trade secrets. Wilson, (N.)		1086
Chemists. Need of professional solidarity among. Parmelee.		1113
Chemists' Club library offers special service.		1089
Chicago Chemists' Club quarters.		937
Entertainment.		1271
Chicago Hardware Co., A. Cer. S. visit.		371
Chicago Section, A. Cer. S.		
Annual meeting.		1131
CHICAGO SECTION, A. C. S.:		
June meeting.		58
Intersectional meeting with Milwaukee Section.		
Announcement.		992
Report.		1086

*Illustrated; (P.), (B. P.)—United States and British patents respectively; (S.)—Synopsis; (N.)—Papers read at society meetings but not printed in full.

- CHILEAN NITRATE:**
- Industry. Refrained. 330
 - Industry regulations. 37
 - Movement of. 101, 641, 887
 - Producers. Condition of. 102
 - Producers to form association. 1136
 - China, Industrial information bureau in. 753
 - Soap trade in. 278
 - China-clay industry, British. 147
 - China-wood O.:
 - Research on. 444
 - Use in varnishes. 470
 - Chlorate cell, Electrolytic, Allen, (P.). 892
 - Chlorobenzene, Aluminum as catalyst in preparation of, Meunier, (P.). 846
 - Chloridizing complex sulphides, (B.P.). 846
 - Chloridizing process, (B.P.). 940
- CHLORINE:**
- Active or available, MacMillan. 1061
 - Electrolytic chlorine: caustic cells:
 - Design of, Allen and Fox, (P.). 847
 - Early commercial types, Barton. 189
 - Fundamentals of diaphragm cell, Moore, I. 1011, II. 1072, III. 1125
 - Symposium on, (N.). 50
 - Townsend cell, Chemical efficiency and concentration of caustic from, Hooker, (N.). 961
 - Industry, Rosenstr., (N.). 1183
 - May have therapeutic value. 1183
 - Shortage affects purification of water supply. 168
 - Chlorperum, Mfr. of, Orton and Pope, (B.P.). 751
 - Chosen, Korea, Cement plant at. 164
 - Cinnamon industry in Ceylon. 684
 - Clay, Rendering plastic, Walter, (B.P.). 893
 - Clay resources of Colorado studied. 1136
 - Clay, Studies in the raw state, Bleiinger, (N.). 78
 - Clayburn Co. reopens Kilgore plant. 1080
 - Cleveland-Cliffs Iron Co. chemical plant. 366
- COAL:**
- Coal-car priority, Chemical industries protect. 166
 - Coal industry of Swansea, Wales. 116
 - Coal-mining laboratory, Carnegie Institute. 1000
 - Consideration of others will help shortage. 305
 - Hydrogenation under pressure, Berkus, (B. P.). 1229
 - Low-temperature carbonization:
 - Carbocoal process, Curtis. 499
 - Discussion of, Parr, (N.). 793
 - Progress in England. 326
 - Fish coals, Monnett. 1246
 - Oxidation of, Godchot, (S.). 340
 - Powdered, Advantages of, Renkin, (N.). 658
 - Second New England I.C.C. coal order. 212
 - Separating ashes from unburnt coal, Krupp, (B. P.). 1270
 - Sulphur in, Powell, (N.). 793
 - Coal-tar chemical industry in 1919, Jones. 681
 - Coal-tar trust formed in Germany. 753
 - Cobalt, Mfr. at Deloro. 52

INDUSTRIAL HYGIENE—Continued:

Prevention of fires and explosions in coal-tar chemical works. Richardson	273
Tanks and pipe lines as causes of accidents. Hoffman	1023
Industrial Notes	88, 176, 220, 264, 300, 348, 759, 808, 903, 1192, 1240
Industrial Relations Association officers	187
Inks, Testing of. (S.)	208
Institute of Chemistry proposed	1230
Institute of Metals Division, A.I.M.E.	767
Columbus meeting, Report	767
International Bureau of Weights and Measures, Paris meeting	306
International Catalogue of Scientific Literature	
Future to be considered	639
Report of conference	943
International Union of Pure and Applied Chemistry, Third meeting, Rome	213
Iron, Electrodeposition of, As repair process	401, 993
Electrolytic, Annealing. Cournot. (S.)	948
Electrolytic, Products	1100
Iron alloys, Decarburizing. (B.P.)	349
Iron ore, Titaniferous, Use of. Heckett. (N.)	366
Iron and steel market	40, 82, 127, 170, 214, 258, 307, 355, 408, 545, 594, 643, 706, 755, 803, 851, 898, 947, 996, 1044, 1093, 1140, 1188, 1235, 1276
IRON AND STEEL:	
Analysis:	
Analysis of ancient armors	975
Detection of nickel in steel. Danheiser	770
High-speed steel. Ward	28
Ironing: (see Metal Protection and Corrosion.)	
Defects:	
Arising during fabrication. Wilson	1209
Cure of flakes by proper heat-treatment. Crouse	329
Inter-crystalline fracture in mild steel. Rosenhain and Hanson. (S.)	1228
Originating in ingot. Wilson	1161
Rails, Shattered zones in. Howard	316
Tests for defects in spring steel	294
Effect of Various Elements:	
Effect of arsenic in steel. McKinney	294
Manganese affects life of ingot molds. Grosclaude. (S.)	891
Nitrogen in steel and erosion of guns. Wheeler. (N.)	366
Nitrogen on steel. Knight and Northrup	1107
Phosphorus distribution between Ac_2 and Ac_3 . Whitely. (S.)	986
Foundry Practice:	
Castings for machine-tool builders. Sherwin and Kelly. (N.)	766
Cupola practice. Moldenke. (N.)	765
Heat treatment of steel castings. (N.)	766
Influence of manganese on life of steel ingot molds. Grosclaude. (S.)	891
Refining high-sulphur iron under carbide slag in electric furnace. Elliott. (N.)	765
Relation of die-casting to foundry practice. Pack. (N.)	768
Steel castings, Practical notes on design and treatment of. Preston	529
Furnaces:	
Blast-furnace hearth. Matheson	867
Electric furnaces for heat treating. Keeney	982
Hardening furnace. Yates. (B.P.)	587
Open-hearth furnace construction. Lambot. (B.P.)	253
General:	
Armor, Analysis of samples of ancient	975
Blades for power shears. Porteous. (N.)	568
Helical springs for heavy duty. Lynch. (N.)	567
Indian iron and steel industry. Perin. (N.)	822
Peace-time uses of war-time lessons. Larkin. (N.)	567
Steel wizards, past and present. Sauveur	633
Heat Treatment:	
Absorption of carbon and sulphur when annealing with coal. Gale. (N.)	766
Annealing electrolytic iron. Cournot. (S.)	948
Cementation mixture. Lutten-schlager. (B.P.)	752
Cementation process. Jashiro. (B.P.)	1138
Commercial heat treatments for alloy steels for structural purposes. Miller	1113
Cyanide hardening due to nitrogen. Brophy and Leiter. (N.)	568
Drawing in salt-peter. Hillman	684
Effect of heat treatment on fatigue strength of carbon spring steel. Stenger. (N.)	635
Electric furnaces for. Keeney	982
Electrical heat-treatment of steel. MacDonald. (N.)	636
Hardening furnace. Yates. (B.P.)	587

IRON AND STEEL—Continued:

Hardening tractor worms. McCloud. (N.)	566
Hardening with aniline dyes. Kaiser. (B.P.)	796
Heat-treating small alloy steel parts. Gilman. (N.)	566
Heat-treatment of chromium-nickel spindles. Smith and Olcott. (N.)	566
Heat treatment of steel castings. (N.)	766
Need of study of changes in structure of hardened steel upon tempering	304
Of high-chromium steel. French	13
Quenching mediums. Hillman. (N.)	567
Relation of high-temperature treatment of high-speed steel to secondary hardening and red hardness. Scott. (S.)	701
Ingot:	
Casting and molding steel ingots. Gathmann. (N.)	367
Cracks in ingots. Giolitti	149
Defects originating in ingot. Wilson	1161
Steel rails from sink-head and ordinary rail ingots. Burgess	1017
Comment. Gathmann	1196
Zones of weakness in solidified ingots. Atchison	280
Metallography: (see also Heat Treatment.)	
Deep-etching experiments on new steel rails. Comstock	1081
Electrometric method for detecting segregation. Mahls. (N.)	561
Metallography of arc-fused steel. Rawdon, Grosbeck and Jordan. Phosphorus distribution between Ac_2 and Ac_3 . Whitely. (S.)	986
Pro-eutectoid ferrite. Clayton. (N.)	367
Segregation in bars for steel tubing. Newell	745
Studies of macrostructure of cast steel. Allison and Rock	383
Surface changes of carbon steels heated in vacuo. Hemingway and Ensminger. (N.)	366
Physical Properties: (see also Heat Treatment.)	
Elastic development of steel. Woodward, Cornell	225
Hardness test. Price offered for	542
Heat content of electric furnace steel. Kuhlmann and Spillman. (N.)	720
Physical properties of arc-fused steel. Rawdon, Grosbeck and Jordan	877
Static notched-bar testing machine	1180
Steel rails from sink-head and ordinary rail ingots. Burgess	1017
Comment. Gathmann	1196
Use of ethed balls in Brinell test	639
Processes:	
Bessemer, Acid:	
The acid bessemer process. McGaffery	103
Electric pig:	
Electric smelting of iron ore with coke. Stig	29
Electric smelting steel plant in Sao Paulo	300
Mfr. of Greenwood. (P.)	120
Pig iron from pyrites cinders in electric furnace. Guédra. (S.)	795
Present status. Keeney	980
Electric steel:	
Gray iron. Mfr. of Stock. (B.P.)	752
Present status of. Keeney	981
Refining steel in Heroult furnace. Bulley. (P.)	750
Open hearth, Acid:	
Balanced reactions in steel mfr. McCance	316
Deoxidizers for steel manufacture. Cain	879
Reduction of silicon in. Yanesko and Wood. (S.)	76
Steel from scrap. Jarvis. (B.P.)	300
Open hearth, Basic:	
Basic open-hearth process. Toy. (N.)	822
Use of high-manganese iron in. Wheaton. (N.)	823
Special Steels:	
Alloy steels for automobiles. Abbott. (N.)	824
Alloy steel, Highly resistant. Johnson. (N.)	508
Automobile steels, British research on. Dickenson. (S.)	1208
Chromium steel, Heat-treatment of. French and Yamauchi	13
Comparative efficiency of combinations of alloys in steel. Cutter. (N.)	636
Copper, Corrosion resistance of. Buck. (N.)	824
High speed tool steel. Cooper. (P.)	588
Nickel-chromium. Hardening. (B.P.)	398
Stainless steel articles. Mfr. of Marble. (N.)	567
Stainless steel, Heat treatment of. French and Yamauchi	13
Isopropyl alcohol from petroleum. Ellis. (N.)	1230
Italy:	
New hydro-electric plants in	528
Water power, Importance of	211

JAPAN:

Aluminum trade of	718
Arsenic trioxide industry	1007
Crude camphor export shipments discontinued	
Dye trade in	274
Silk production in	109
Vegetable oil industry in	1270
Japanning process. Jensen. (B. P.)	517
Jeffries-Norton liquefaction system	
Kaolins, Elutriation tests on American. Schurecht. (S.)	207
Kauri gum industry in New Zealand	1197
Kilns, Dressler tunnel	78, 660, 837
Labor, Conservation of. Wallace. (N.)	1054
Laboratories:	
Coal-mining laboratory, Carnegie Institute	1090
Industrial research laboratories in America	120
Novel laboratory for industrial research. (Dorr Co.)	496
Ladies, Steel, Repairing lips and bottoms of	1226
Lake Superior milling and smelting practice	365
Lakes, Mfr. of. Lance. (B.P.)	1037
Lard compounds, Research on	445, 484
Latent heat data needed	448
Leaching chloridized lead-silver ores. (B. P.)	253
LEAD:	
Desinking process. Harris. (B.P.)	586
Extraction from complex sulphide ores. Amalgamated Zinc, Ltd. (B.P.)	761
Extraction from ores. Elmore. (P.)	798
Plating from sodium hydroxide baths. Mathers. (N.)	724
Lead poisoning, Susceptibility of women to	603
LEATHER:	
Albanian factory changes hands	1103
Artificial:	
And coated fabrics	487
Mfr. of. Miller. (B.P.)	349
Mfr. of. Zignone. (B.P.)	350
Recent patents on	488
Determination of HCl and chlorides in. Thomas and Frieden. (N.)	616
From rabbit skins	968
Glazed kid leather. Blats. (N.)	1083
Leather industry. Wilson	457
Leather waste for heels in Germany	801
Lizard-skin industry in India	1074
Relation of animal products industry to	488
Tanning: (see Tanning)	
Use in organs and player pianos	303
Use of dyes in leather. Roberts. (N.)	616
Leather Section, A. C. S. Meeting	613
Leathin, Mfr. of. Baumann and Grossfeld. (B.P.)	941
Legal notes. Judgment affirmed against chemical companies	214
Legal notes. When a workman overdoes himself. Sherlock	117
Legal notes	32, 60, 204, 242, 289, 327, 375, 520, 727, 834, 888, 920, 985, 1030, 1076, 1129, 1177, 1222, 1250
LEGAL NOTES: By Wellington Gustin.	
Agreement with promoters not the contract of the corporation subsequently organized	38
Bills of lading construed in light of contemplated adventure	1224
Buyer and seller held in default where shipment is prevented by embargo	728
Chemical company liable for deaths of boys bathing in poisonous pool	1223
Claims of noxious ammonia and insufficient content not allowed by court	1130
Company has right to replace old system to preserve investments	1031
Compensation for death hastened by aggravation of disease due to explosion	520
Contract where "Ton" means 2,000 lb.—Rule may be changed by agreement or custom	376
Corporation may not replevin formulas and stock	242
Correspondence and telegrams held to constitute a valid contract	60
Court holds invention by employee not within his contract assigning all invention rights	376
Decision on patents of Cottrell and Speed	327
Decree against Continental Sugar Co. modified—Byproduct plant is abandoned	285
Debtor's check not payment until check is paid	204
Delivery delay excused by mandatory order from Government where contract so stipulates	60
Directors held liable for paying unwarranted dividends	1177
Establishing the market value of a product—The damage to a purchaser for resale	204
Fertilizer manufacturers should watch their sales contracts	1129
Fraudulent representations do not make fertilizer fraudulent under statute	985

*Illustrated; (P.), (B. P.)—United States and British patents respectively; (S.)—Synopsis;

(N.)—Papers read at society meetings but not printed in full.

LEGAL NOTES—Continued:

—Hair-line cracks on ingot steel not breach of warranty against serious surface defects	1030
—How a loosely-drawn contract caused loss to glass manufacturer	185
—Indorsement on check insufficient to discharge whole claim in dispute	985
—Injury to employee from fumes in factory	1076
—Liability for loss in shipment due to leakage	1222
—Logan patent for cryogenic apparatus held not infringed	1223
—Loss in shipment of menthol acetate depends on duty to unload under contract	580
—Meaning of c.i.f. as distinguished from f.o.b.—Rules governing such contracts of shipment	834
—Novel method for calculating damages by jury—Prior agreement vitiates such verdict	242
—Obligations upon agreement to surrender contract of exclusive right to handle product	520
—Option in a chemical contract must be exercised within a reasonable time	1076
—Oral agreements excluded when written contract is neither uncertain nor ambiguous	920
—Orstein process of chlorinating water upheld in Federal Court	1177
—Palmer Potash Products Co. v. Nebraska Potash Works Co. controversy	727
—Plant must be operated not to interfere with health of neighboring residents	1031
—Purchaser should use good faith in making resale of goods not up to specifications	328
—Recovery of salary and expenses not bar to action for damages	242
—Seller must prove product possessed quality desired where such is known to him	985
—Seymour Mfg. Co. obtains large judgment—Agreement not in restraint of trade	375

Mees, Dr. C. E. K., receives research medal	1272
Meetings, Coming, and Events	44, 88, 132, 176, 220, 263, 313, 360, 408, 452, 500, 548, 712, 759, 808, 856, 904, 952, 1000, 1048, 1096, 1144, 1192, 1240, 1280

METAL PROTECTION AND CORROSION:

—Copper steel, Corrosion resistance of, Burk, (N.)	824
—Corrosion of iron and steel, Richardson, (N.)	50
—Corrosion prevention in petroleum refining vapor systems, Mathews and Crosby	1122
—Experiments on corrosion of iron and steel, Richardson	243
—Influence of Cu, Mn and Cr on corrosion of their iron alloys, Richardson, (N.)	724
—Oxygen the prime factor in corrosion, Richardson	23
—Solution of metals in acids, Richardson, (N.)	725
Metals, Failure under internal or prolonged stress, Faraday Society to hold symposium on	886
Methane from CO and H ₂ , (B. P.)	1132
Methanol:	
—Causes death of nine men at Edgewood Arsenal	639
—Methanol plant for British Columbia, Mfr. from cellulose material, Clasper, (B.P.)	1041
Methyl alcohol: (see Methanol)	
Methylamines from beet sugar molasses, Mexico, Clearing up—With soap, Boyer	423
Mexico, Clearing up—With soap, Boyer	180
Mexico City trade conference	1272
Mica industry in India	960
Michigan, Univ. of, Evaporator experiment station at, Badger and Shepard	159
Microscope industry, in support of American, Howe	226
Midvale Steel & Ordnance Co. report	356
Milk, Electrical sterilization of	22
Milk plants in Washington	353
Milling industry, Chemical problems in, Milwaukee Section, A. C. S.:	1005
—Intersectional meeting with Chicago section:	
—Announcement	982
—Report	1086
Mineral deposits, Apparatus for locating, Hols	268
Minerals Separation, Mitigation	123
—Contempt proceedings dismissed	123
—Federal Trade Commission hearings at San Francisco	124
—Loses another appeal	2544
—Case appealed	589
—Dismissal of contempt proceedings sustained	1183
—Application of ideas of unfair trade practice to	87
Mining and Metallurgical Society gold medal presented to E. A. Cappellet Smith	993
Moisture determination in dry CO ₂ -free air, Montgomery	937
Molasses, Byproducts from	423
Molybdenum during 1917-1919, Hess	1029
Molybdenum, Mfr. at Fansteel Products Co.	537
Molybdate, Occurrence, detection and determination of, Bonardi	205
Monanto Chemical Co., Explosion at, Montevideo, New sulphuric acid plant for	1272
Morocco, Phosphate rock deposits in, Martin	840
Motion picture film, Developing, printing and assembling, Chapman	606
—	97

N

Naphthalene, Determination in crude naphthalene and tar, Pastre	286
Naphthalene, Hydrogenating, Schroeter, (B. P.)	1181
Natalite as motor fuel	255
National Academy of Sciences to have new home	898
National Association of Purchasing Agents—Chicago meeting, Program	593
National Council of State Boards of Engineering Examiners formed	991
NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES:	
—Preliminary program for sixth exposition	165
—Ceramic day announcement	306
—Program	412

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES—Continued:

—Descriptive list of exhibitors	413
—Report:	
—Opening addresses	589
—Sidelights on the exposition	558
—Fuel economy symposium	558
—Industrial management and materials handling	663
—Chemical engineering symposium	664
—Ceramic day	675
—Suggestions to exhibitors, Abrams	718
National Marine Show, Chicago	594
National Research Council:	
—And National Academy of Sciences to have new home	898
—Research information bureau	1040
Nebraska potash industry, Present status of	575
—Situation improves	638
Nela Park, A. E. S. visit	726
Nela Research Laboratories, Reorganization of	305
New Brunswick, Oil shale prospects in	602
Newcastle steel works expands	1313
Newfoundland, Pulp and paper developments	639
New Haven Section, A. C. S.:	
—October meeting, Lead	943
New Iberia salt mines	1301
New Jersey Chemical Society:	
—Third annual meeting	991
—December meeting, Isopropyl alcohol	1250
New Jersey Clay Workers Association:	
—Trenton meeting, Report	78
New York Section, A. C. S.:	
—Special joint meeting, Government inventions	817
—October meeting	864
—November meeting	1039
New York Section, A. E. S.:	
—Special joint meeting, Government inventions	817
New Orleans sugar machinery foundry, Stanley	914
New Zealand, Prohibits exportation of adulterated kauri gum	284
—Sugar situation in	251
Niagara Falls Section, A. E. S.:	
—November joint meeting	1044
Nickel-cobalt alloy Ductile, Fink, (P.)	749
Nickel oxide, Recovery from scrap, (B.P.)	397
Nickel-plating solutions, Use of hydrofluoric acid in, (N.)	125
Nickel wire resistors for electric furnaces, Fitzgerald and Moyer, (N.)	720
Nitration of hydrocarbons, Hough, Savage and Van Marle	666
Nitrocellulose, Mfr. and uses of, Schlatter, (N.)	591
—Correction	704
Nitrogen in steel, Wheeler, (N.)	366
NITROGEN FIXATION:	
—British nitrogen production plans, Hamer	22
—Determination of nitrogen oxides in processes for, Taylor	1112
—Fixation in soil by inoculation, Emerson	606
—Haber method, Comment, Tucker	48
—Nitrogen Corporation bill to be pushed	1233
—Operation of Government nitrate plants urged	302
—Synthetic ammonia: (see under Ammonia)	
Nitrogen oxides, Determination in nitrogen fixation processes, Taylor	1112
Nitrogen pentoxide, Thermal decomposition of, Daniels, (N.)	562
Non-ferrous metal market	40, 82
Northwestern Terra Coita Co., A. C. S. visit	370

Steel & Tube Co. of America, A.C.S. visit	837		
Steel Treating Research Society: (see American Society for Steel Treating)			
Sterilizing food, Process for, Pape, (B.P.)	539		
Strong Paper Co. changes name	992		
Student, Putting responsibility on, Richards	1115		
SUGAR:			
—Application of classifiers, Horn, (N.)	564		
—Beet sugar industry, Chemical problems of, Dahlberg	421		
—Brazilian industry	887		
—Canadian industry	371, 401		
—Changes in sugars during refining, Blake, (N.)	564		
—Chemical control in sugar industry, Osborn, (S.)	424		
—Chemistry in sugar industry	1008		
—European production	1082		
—French sugar industry, Murphy, (N.)	564		
—French sugar situation, Nottin, (S.)	537		
—Laboratory methods, Bates, (N.)	564		
—Mauritius production, 1920-1921	908		
—New plant at Mt. Pleasant, Mich.	895		
—Protection of raw sugar from mold, Purifying sugar juices, von Wiernas-Kowalski (B.P.)	399		
—Refining raw sugars without bone black, Coates, (N.)	35		
—Relation between molasses and, Herrel, (N.)	564		
—Sugar-beet raising to be resumed in Alberta	1200		
—Suga machinery founding at New Orleans plant, Stanley	12		
—World's crop estimates, 1920-1921	914		
Sugar Chemistry Section, A.C.S. Meeting	1214		
Sugar cane fiber, Hydrolysis of, Sherrard (N.)	564		
Sulphide ores, Roasting in presence of CO ₂ , Foss and Halvorsen, (P.)	120		
Sulphite waste liquor, Fats from, (B. P.)	1133		
Sulphite waste liquor, SO ₂ recovery, & haefor, (P.)	301		
Sulphonic esters, Melamid	796		
SULPHUR:			
—In iron, Removal by refining under carbide slag, Elliott, (N.)	765		
—Portland, Ore., a distributing point for	943		
—Purification of, Hodd, (B.P.)	299		
—Recent advances in industry, Bacon, (N.)	1200		
—Stellian, Prices fixed on	187		
—Sulphur should be conserved	702		
—Use in paper pulp digester liquor	509		
Sulphur dioxide:			
—Production at metallurgical plants, Laist and Frick, (P.)	344		
—Recovery from furnace gases, Bustie, (P.)	588		
—Use in candy prohibited in Pennsylvania	60		
Sulphuric acid:			
—Fume problem, Withrow, (N.)	1200		
—New plant for Montevideo	840		
—Plant design, Quinan, (P.)	847		
—Purifying, Davis, (B. P.)	1133		
Superpower survey, Chemical industries to be represented on	257		
Swansea, Wales, Coal industry of	116		
SWEDEN:			
—Electro-metallurgical production of iron, steel and alloys, (S.)	701		
—Market for sodium sulphate in	802		
—Profits of government water-power administration	580		
—Wood pulp industry in 1919	31		
Swenson Evaporator Co. wins suit	81		
Switzerland, American shoes in	1202		
Synopsis of recent chemical and metallurgical literature	76, 119, 207, 251, 288, 346, 395, 537, 585, 701, 748, 795, 845, 891, 939, 1227, 1268		
Syracuse Section, A. C. S.:			
—December meeting	1271		
T			
Talc, Uses of, Ladoo	235		
Talc in fire-resistant paint, Ladoo	689		
Tank car dome covers should be secured	226		
Tanks and pipe lines as causes of accidents, Hoffman	1023		
TANNING:			
—Accelerating by means of air, (B.P.)	209		
—Canadian Electro Leather Industries use electricity in	1090		
—Chemical control of tannery, Orthman, (N.)	615		
—Chemistry of processes	458		
TANNING—Continued:			
—Comment on Wilson's and Kern's data, Thomas, (N.)	616		
—Effect of chrome liquor concentration upon adsorption by hide, Thomas and Kelly, (N.)	613		
—Extracts, Chute, (N.)	468		
—Fertilizer from tannery waste sulphide liquors, Kadiash, (N.)	614		
—Influence of non-tannin acids on tannin content of tan liquors, Gladin, (N.)	615		
—Materials:			
—From waste sulphite liquors, (B.P.)	253		
—Synthetic, B. A. S. P. (B. P.)	1133		
—Synthetic, Koetsie, (P.)	347		
—Synthetic, Melamid, (B.P.)	35		
—Synthetic, Melamid, (B. P.)	1239		
—Synthetic, Worms, A. G. (B. P.)	1268		
—Process, Brenner, (B.P.)	1037		
—Swelling and falling off of white hide in vegetable tan liquors, McLaughlin and Porter, (N.)	615		
—Tannin analysis, Wilson, (N.)	613		
—Tanning by electroendosmosis, (B.P.)	797		
—Tanning, Rosakins	1083		
Tannolactone, Mfr. of, Kolshorn, (B.P.)	1037		
Tar, Coke-oven, As fuel	336		
—Extracting from vapors, Barbet, (P.)	847		
—Primary low-temperature, Characteristics of, Fischer	70		
Tariff Commission and industry, Culverston, (N.)	800		
Tariff hearings to begin Jan. 6, 1185	1232		
Tasmania, Electrolytic zinc works in	234		
TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY:			
—Fall meeting, Saratoga Springs:			
—Program	167		
—Additions to program	213		
—Report	508		
—Temperature conversion tables, Sauvour	1075		
—Terra cotta glazes, Effect of composition of kiln gases on, Orman, (S.)	251		
Texas Gulf Sulphur Co. loading plant burned	705		
Textile fabric, Artificial, Drut, (B.P.)	752		
Thermal conductivity data needed	448		
Thermal emissivity data needed	448		
Thermite welds on cast-iron	1080		
Thermochemical data needed	448		
Thermo-electricity progress	69		
Thiocyanogen, Free, West	925		
Thionyl chloride, Waterproofing cellulose materials with, Moeller, (B.P.)	990		
Tier-Lift industrial truck	296		
TIN:			
—Electrolytic refining of, Kern, (N.)	723		
—Plating from alkaline baths, Mathers and Bell, (N.)	723		
—Refining with chlorine, Bonnard, (B.P.)	1037		
Tin oxide mfr., Macanochie, (B.P.)	397		
Tinplate for canning, Tests of base steel plate for	543		
Titanium pigment industry in Norway (S.)	845		
Tobacco industry	776		
Townsend cell, Chemical efficiency and concentration of caustic and salt from, Hooker	961		
Trade practice, What constitutes unfair	191		
Trade secrets, Chemist and, Wilson, (N.)	1086		
Transformer oil, Mfr. of, Melamid, (B.P.)	796		
Trunching machine	1228		
Triplex Safety Corp., Safety glass mfr.	465		
Tripoli industry active	944		
Truck, Tier-Lift industrial	296		
Tubes, Metal, Mfr. of, Mills, (B. P.)	1270		
TUNGSTEN:			
—Coolidge wrought tungsten patent valid	121		
—Historical notes on refining in Europe, Matignon	696		
Tungsten alloys, Mfr. of, Deppeler, (P.)	750		
TURPENTINE:			
—And rosin production	866		
—Barrels, Glueing	832		
—From British Columbia firs	338		
—Tanks and cars, Painting	887		
U			
Ultramarine, Mfr. of, Lande, (B.P.)	1037		
Ultra-violet rays, Effect on eye, Kindall	1071		
Union Bag & Paper Co. plant	510		
Union Sulphur Co., A. I. C. E. visit	1201		
United Tank Car Co., Growth of	304		
United Gas Improvement Co. on heat unit basis	256		
U. S. Bulletin on open shop	250		
Urea, Mfr. of, Badische, (B.P.)	941		
Uruguay, Mfr. of superphosphate from bone	801		
Utah, Non-metallic resources of	1244		
Utah University mining and metallurgical society	1087		
V			
Vacuum pump, New type	119		
Valerates, Alkali, Mfr. of, (B.P.)	34		
Vanadium industry during 1918, Hess	1063		
Vanilla production in Madagascar	1267		
Vanillin, Mfr. of, Weiss, (P.)	540		
Vapor pressure data needed	447		
Varnish fume recovery, Jones	771		
Varnish industry, Toch	469		
Vaseline factory, French	1203		
Vegetable oil industry, Bailey	441		

*Illustrated; (P.), (B. P.)—United States and British patents respectively; (S.)—Synopsis; (N.)—Papers read at society meetings but not printed in full.

Vegetable oil industry in Japan.....	109
Vegetable refuse, Utilizing. (B. P.).....	1228
Virginia-Carolina Chemical Co. report.....	256
Vitamines, Chemistry of. Seidell. (N.).....	1041
Vulcanization: (see under Rubber)	
Vulcanized fiber. Robinson. (N.).....	1084

W

Wabblers, Thermit welded, Manganese addition increases life of.....	337
Wall Street explosion, Type of explosive used. Mardick.....	717
Wall paper, Mfr. at Sears, Roebuck & Co.	840
Walnut shells, Poultry charcoal from. Glaze and Stringfield.....	368
War Minerals Relief Act, Payne hears plea for passage. Thau.....	1065
Washington Section, A.C.S. (Chemical Society of Washington):	
—October meeting, Automobile exhaust gases.....	942
—November meeting, Vitamines.....	1041
—December meeting, Motor fuel.....	1231

WASTES, INDUSTRIAL:

—In relation to water supply.....	882
—Research and. Hessenbruch. (N.).....	498
—Treatment of. Eagles.....	438
Water Power Act regulations being drafted.....	306
—Hearings on.....	306
—Changes being made.....	351
Watch oil from petroleum.....	886
Waterproof paper. Heilbronner. (B.P.).....	751
Waterproofing cellulose with thionyl chloride. Moeller. (B.P.).....	990
Water-purifying chemicals, Priority on.....	305
Water softener, Lime-soda ash, continuous type, Data on operation of. Catherman and Fisher.....	526
—Corrections. Fisher.....	717
Wave power transmission.....	913
Wedge optical pyrometer.....	925
Weir measurement of liquids. Chase.....	1224

WELDING:

—Cast-iron thermit welds.....	1080
-------------------------------	------

WELDING—Continued:

—Gasoline condensers by oxy-acetylene process.....	537
—Physical properties of arc-fused steel. Rawdon, Groesbeck and Jordan.....	677
—Metallography of arc-fused steel. Rawdon, Groesbeck and Jordan.....	777
—Metal sheets. (B.P.).....	893
—Western chemical and metallurgical field. A. 136, 1241.....	371
Western Electric Co., A. Cor. S. visit.....	1039
—November joint meeting. A.C.S.	211
Western Silica Co.....	100
Westminster Abbey, Engineers and scientists in. Mehren.....	59
What can be done with it?.....	665
Whitaker-Pritchard process of destructive distillation. Pritchard.....	302
Whitehead made Commissioner of Patents. Whitney awarded Perkin Medal.....	1271
Wild-Barfield electric furnace. Wild.....	689
Wilmington and chemical industry.....	1083
Wire-baking electric oven.....	285
Wisconsin University revises chemical work.....	1088
Wolfryn process for electrical treatment of seeds.....	181

WOOD:

—Coloring to simulate age. Simon. (B.P.).....	349
—Fire-resistant coatings for.....	147
Wood alcohol: (see Methanol.)	
Wood extracts for tanning and dyeing. Chute. (N.).....	468
Wood fibers, Variation in length.....	367
Wood distillation:	
—Canadian industry.....	153
—Recent developments in hardwood distillation industry. Hawley.....	466
Wood preservation:	
—By chemical treatment. von Schrenk and Kuehn. (N.).....	942
—Compound mercuric chloride solution for. Bub. (B. P.).....	1229
—Light creosote oils in.....	56

WOOD PRESERVATION—Continued:

—Preservatives must be water soluble.....	1041
—Process. (B. P.).....	1181
—Sodium fluoride vs. zinc chloride. Hunt.....	1123
Wood waste utilization in Pacific Northwest. Strong.....	279
Wool, Artificial, From cotton waste.....	696
Wool, Scouring, Banners. (B.P.).....	989
Wool waste, Chemists studying uses of.....	98
World Trade Club of St. Louis.....	944

Y

Yacca gum production in South Australia.....	1154
--	------

YEAST:

—Manufacture at Fleischmann Co.....	831
—Preserving. Robinson. (B.P.).....	31

Z

ZINC:

—Electric furnace for. Louvrier. (P.).....	348
—Electric furnace smelting, Status of.....	983
—Electrolytic, Purifying solutions for. Sulman and Field. (P.).....	209
—Electrolytic plant of Consolidated Mining & Smelting Co. of Canada. Chapman.....	227
—Electrolytic process. (B.P.).....	350
—Electrolytic works in Tasmania.....	234
—Extracting from complex ores. Skinner. (P.).....	798
—Removing cobalt from zinc solutions. Avery and Williams. (P.).....	749
Zinc chloride consumption in wood preservation.....	1123
Zinc chloride from zinc ores. Cameron, Cullen and Hyde. (P.).....	988
Zinc oxide, Mfr. Maconochie. (B.P.).....	397
Zinc sulphide, Mfr. of. Clerc and Niboul. (B.P.).....	1037
—Mfr. of. Coppet. (B. P.).....	1281
—Mfr. Heilbronner. (B. P.).....	1209
Zirconium ores, Determination of zirconium and titanium in. Lunell and Knowles. (B.).....	396

Lessons From Engineering Council For the New Federation

TWO questions which are bound to enter the mind of any engineer considering the pros and cons of the Federated American Engineering Societies are these: "If Engineering Council is a success, why should the proposed Federation supplant it? On the other hand, if Engineering Council is a failure, why should the Federation be organized along lines so nearly parallel?" Undoubtedly these thoughts were in the minds of many delegates to the organizing conference held last month in Washington, even if they were not directly stated on the floor, for at least three very influential delegates spoke in defence of Engineering Council, denying its ineffectiveness, yet explaining why it had not attained full measure of success.

It should be immediately pointed out, however, that the second question involves detailed information of the constitution, organization and personnel of both the Council and the Federation—upon inquiry it may be established that the two bodies are fundamentally different and the premise stated in the query therefore entirely unjustified. Such an investigation is not the present object; it is rather to inquire into the reason why Engineering Council did not attain its expected amount of influence. This known, some of the reefs and shoals along the course of the new organization will be charted, and a voyage steered accordingly.

Engineering Council, it will be recollected, is the child of the United Engineering Societies, which, in turn was formed by the four so-called Founder Societies—Civil, Mining, Mechanical and Electrical Engineers—and, quoting their official literature is an "organization of National Technical Societies of America, created to provide for consideration of matters of common concern to Engineers, as well as those of public welfare in which the profession is interested, in order that united action may be made possible." The American Society for Testing Materials and the American Railway Engineering Association are also member societies. The executives of each of the member societies appoint representatives, who have subdivided their number into various committees, the personnel of which do whatever is done along their delegated line of activity. Their funds have been meager, being limited to some \$13,000 annually contributed by the member societies.

Well informed engineers have characterized Engineering Council as an imposing body which did nothing. This is doubtless too harsh a criticism, for the Council has done a great deal of good work—much of it in a pioneering way, by trial and error. Yet unquestionably there has not been the activity in any line that was expected nor hoped. By its mode of organization about all it could do was to start the ball rolling along a desired path, and

it had no means of reaching out into the great body of engineers in this country to get them behind the ball and keep it rolling faster. Consequently and naturally it settled back into rest.

In other words, the insurmountable defect in Engineering Council was its lack of connection with the "rank and file." All its admitted shortcomings can be ascribed to that one fact. The individual engineer knew very little about Engineering Council—he had no part in its actual organization beyond his collective urge that engineers organize nationally for economic ends. If he knew anything at all about Engineering Council, he probably felt that it should actively prosecute welfare work without any further help from him; was it not the body of men selected to do that particular job? Being thus built from the top down, it had an imposing head, but lacked a numerous body of men intelligently interested in its aims. Lacking this, it lacked the necessary funds even to operate effectively, let alone to sustain and widen the interest. Consequently only the close insiders actually knew what those at the head were doing, or what difficulties they were encountering.

A moral can easily be drawn from this little bit of history. The new Federated American Engineering Societies must have the interest of its ultimate members—the individual engineer. Only if it has this in good measure can any great success be attained. Its organization should be unrestricted, so that necessary movements may not be hampered; yet on the other hand, the organization should not be magnified as is the clear tendency in the large national societies to a point where it will be nothing but a large income with little net output except printed matter. Frequent and ready circulation from the top down, and the bottom up, is as necessary for right action, as good blood and exercise is for clear thinking.

Colorado Breaks With The Bureau of Mines

UNENVIABLE notoriety is again the portion of the Colorado School of Mines in forcing upon the Bureau of Mines a decision to sever relations between the two institutions and remove the Golden station of the Bureau from the State of Colorado. A report of the break appears elsewhere in this issue. Rumors differ as to whether the action was precipitated by President Alderson or by the Board of Trustees, but the official communication delivered to the superintendent of the station by Acting President Palmer, Alderson being absent in Europe, lays the responsibility at the door of the Board. That may be an inconsequential detail; but there is no question as to the temper of the mining and metallurgical leaders of the State regarding the inconsiderate folly of the act which has deprived Colorado of

federal recognition and co-operation. While they regret the loss they can only endorse the Bureau's decision and hope that some day Golden will clean house and restore to the School of Mines the prestige which it formerly enjoyed and which is still the pride of early graduates.

Golden may argue that it did not eject the Bureau, but that it suggested merely a change of quarters from Engineering Hall to the experimental mill. The transparency of this subterfuge will be evident to those who are familiar with the location of the mill in the creek bottom and its unfitness for use in the delicate and exact scientific work conducted by the Bureau. Perhaps this was an adroit and cunning attempt to turn to some useful purpose a building that has always been a white elephant! However that may be, the Bureau will have no difficulty in finding welcome quarters in some other State, but it is a pity to interrupt important work and spend money in the unpleasant task of moving a large laboratory to a new location where the process of taking root and resuming investigations must be repeated.

Chemical Societies In Industrial Works

WE ARE indebted to Dr. GEORGE E. EWE, chief chemist for the H. K. Mulford Co. of Philadelphia, for an interesting outline of a chemical society organized and maintained within that company's pharmaceutical and biological establishment. It began in June, 1914, with membership open to any employee, but preferably to those having chemical training. It meets on Friday afternoons whenever called, and papers relating to general and specific subjects are presented; discussions are held, the chief business of the meeting to follow is announced, and so are any new processes or products undertaken in the works.

The results have been, he assures us, very encouraging. A wide variety of subjects has been presented and considered, most of which, of course, have a pharmaceutical turn. And quite apart from the illumination contributed by the various papers, the discussions have proved to be helpful in co-ordinating the various departments and in establishing an *esprit de corps* throughout the organization.

The difference between an establishment in which all the members of the staff are interested and curious, where all pull together, and one in which each person works for the pay there is in it but without either interest or good will, is sometimes described as "all the difference in the world." The expression is hardly adequate. If members know what their fellows are doing this begets teamwork. The opportunity to talk things out and learn the reasons why things are done is the best possible insurance against misunderstandings. And misunderstandings are the worst of nuisances. Innovations may be presented and explained and the consequent rumble of grumble over anything new is avoided. It also gives a man who is not in an executive position a chance to suggest betterments where the operating force can hear them, and if the operating force feels convinced that the proposed changes are needed it makes a more forceful impression upon the main office if the staff recommends it than if the man who originates the idea tells it to the wrong person in authority. Again, if new instructions are given, whether they be of a general or a specific nature, they

can be explained to substantially all to whom they should be explained. Sometimes an otherwise excellent man will get a grouch over any kind of a proposed change, but he can't very well hold fast to his grouch when everybody else understands and favors the measure. One of the greatest advantages of a works chemical society is that its members get to know one another, and personal acquaintance of this sort helps to avoid disputes. "How can I hate a man," asked CHARLES LAMB, "if I know him?" And it gives a scientific turn to the scientific men who spend their days in an industrial concern engaged in scientific work.

We have come across a number of these chemical societies within works of late, and usually they are of great value. That is, they are, unless they are dead. Sometimes such societies haven't anything but a name, like the "chemical laboratory" in a boarding school for young ladies that was exhibited to us with gusto to prove how progressive the head mistress was. It was a laboratory in design, but on closer observation we noted that it lacked gas and water connections and that the enclosed spaces were used for the storage of stationery. We have seen "research laboratories" very much like that, too. But a live chemical society within an establishment is worth while, if the establishment is not too small. We are not sure whether bigness may serve as an inhibition or not, but wherever it is feasible to establish such an organization we believe it is worth while. The main thing is that it be a live institution to arouse the scientific interest of the technically trained men employed. Such societies have to find themselves and find their proper level. The meetings in the research laboratory of the General Electric Co., for instance, would doubtless be over the heads of some technologists. So would those at the Mellon Institute or the Tuesday afternoon symposia at the Little laboratory in Cambridge. It is a delicate task to organize such a society, making it neither too high for the interest of its restricted number of members nor too low for their self-esteem. But it is a good thing to have.

British Nitrogen Production Plans

DURING the war Great Britain, like the United States, laid elaborate plans for fixing atmospheric nitrogen; but owing to confusion and delays the projected plant failed to materialize before the Armistice removed the immediate necessity for its construction. The result, as Mr. HAMER explains elsewhere in this issue, was that Billingham amounted to little more than a site, a few roads, some foundations and temporary structures. While this is in sharp contrast to our own Muscle Shoals, it is not certain that the United States is now in nearly so happy a position as Great Britain when their respective post-war nitrogen problems are concerned. The British have solved theirs, while ours not only remains unsettled but has become a basis for controversy.

Having no war-time investment in a plant of questionable present use and value, the British found no insuperable obstacle to an arrangement with Brunner, Mond & Co. whereby that firm has organized Synthetic Ammonia & Nitrates, Ltd., to acquire Billingham, retain the Government's technical staff and proceed with the erection of a plant for the synthesis of ammonia. British national safety is thus amply assured, and a

happy solution is apparently reached for domestic production of fertilizer and, if needed, explosives.

In addition to this arrangement between the Government and private industry, announcement is made also of a new British company which has purchased rights for the Claude high-pressure process, for which claims of unusual economy are made. No operations have been started in England but the projected plant will add greatly to Britain's independence in nitrogen fixation for both peace and war.

The Philosopher's Opinion Of the Scientist

THE responsibility of the chemist and his obligation to civilization come to our attention with increased force in the words of the great English philosopher and mystic, WILLIAM RALPH INGE, as delivered before the Chicago Chemists Club by JOHN SMALE, of Lewis Institute. In speaking of the future of the human race Inge says: "Science, I think, is our best hope."

This confirmation by an enlightened man of the scientist's opinion of his calling must be considered something more than a mere idea in the abstract. It assigns to him the task of developing and expressing that which is within for the advancement of the race to higher things, rather than the baser and more usual labor of securing something from without. It classifies him as a producer wholly above the overcrowded realm of sycophantic beings who seek returns without creative effort. It is a position to be envied above all others, and once attained, can be held only by continual introspection for the prevention of parasitic or piratical tendencies.

Organized Labor and The Steel Industry

THERE is a new turn in labor union affairs as relates to the great stumbling block, the iron and steel industry. The American Federation of Labor and the Amalgamated Association were "on the outs" as to jurisdiction, but the latest news is that the differences have been adjusted, or rather compromised. As to the method, report has it that Mr. GOMPERS has accorded the Amalgamated Association a 51 per cent vote on the general committee for organizing iron and steel workers authorized at the recent Montreal convention, to succeed the committee of the federation which conducted the late strike in the industry.

Presumably this arrangement was made because it was the best that Mr. GOMPERS could get. The Amalgamated Association's officials had ambitions looking to the whole industry being organized by that body, but Mr. GOMPERS could well say to it "Go get a reputation," as of late it has controlled only portions of certain branches of the industry, a really insignificant percentage of the whole.

It should be generally understood that this matter of attempting to "organize" the iron and steel industry is a very important one to the American Federation of Labor. This is not, by any means, because the industry offers a fertile field for the organizers. The federation management knows quite well, from past experience and from scrutiny of present conditions existing, that it does not. What it does see, as was frankly admitted at the annual convention of the fed-

eration in June, 1918, when it was resolved to attempt to organize the iron and steel industry, is that this great nonunion industry stands as the greatest barrier to the further progress of the federation's movement. Why should any nonunion industry be organized if the iron and steel industry is not? If that industry can remain nonunion, so can the others. The industry is a positive force for nonunionism or the open shop. If the industry could be made simply to disappear entirely, that would be the next best thing to its becoming union.

Rumors are thick, and probably correct, that the organizing attempt will be directed wholly or very largely against the United States Steel Corporation, which makes about 44 per cent of the country's steel, rather than against the industry as a whole. The management of the United States Steel Corporation should feel complimented, as doubtless it does, though the compliment is one it could be comfortable without. It being a case of a stumbling block, the singling out of the Steel Corporation is suggestive that the bid of the Steel Corporation for the loyalty of its workmen is particularly high.

If that is the case, however, what has the American Federation of Labor, or the Amalgamated Association, which it is understood will be a 51 per cent factor in the organizing campaign, to offer in competition? As to money, the iron and steel workers know they are well paid, by comparison with rates paid in other industries, and very much so by comparison with the wages paid for many months past to large classes of railway employees. As to social service, playgrounds, visiting nurses, hospitals, home gardens and other things, the iron and steel industry, including the ore and coke branches, has done a great deal. Only recently the Steel Corporation has put into operation a system whereby any one of its employees can own his own home, by paying down 10 per cent of the cost price and paying the remainder from his wages.

The organization methods employed in connection with the iron and steel strike of last September are wholly to be condemned, but from the practical standpoint they offered the best chances of success, and yet the affair failed. The appeal was to the least intelligent of the workers and there does not seem to be any means whereby those men can be fooled again, while as to the skilled men, they are in the main very well contented.

The Relative Demand For Cooks and Chemists

IT HAS been remarked lately that the day of the chemist has arrived; in fact some of us were of the opinion that it was already high noon. There is evidence, however, from some quarters that the dawn is just breaking. For example the Civil Service Commission of New York City would like very much to find a first-class cook; and for culinary ability of a sufficiently high order it will pay a stipend of \$2500 per annum. Likewise the city is in need of the service of a chemist skilled in food and drug examination, but his value is marked down to \$1800 per annum. Proceeding further we discover that a competent laboratory assistant in pathology may secure a fine position at \$950 per annum. Comparisons are odious; but no one doubts that we need good cooks.

Western Chemical & Metallurgical Field

Smelters Not Responsible for Smoke Nuisance in Salt Lake City

For several years past Salt Lake City, Utah, has been vying with Pittsburgh for the distinction of being the smokiest city in the world. Many of the influential residents believe that the nearby smelters contribute appreciably to the smoke nuisance, on the theory that the gases discharged from the smelter stacks float over the city in a heavy blanket which prevents smoke from the city chimneys from rising.

It may be remembered that the Garfield smelter of the American Smelting and Refining Co. is sixteen miles west of this city, the Murray smelter of the same company is eight miles south, and the Midvale smelter of the United States Smelting Company, twelve miles south. The smoke conditions at the two latter plants were discussed in detail in *CHEMICAL & METALLURGICAL ENGINEERING* for June 23, 1920, page 1145. While conditions at the Garfield smelter are not nearly so good, under normal operating conditions a relatively small amount of solid matter is discharged from these stacks. The toxic constituent of the discharge is SO_2 , yet it was shown in the article just quoted that even in the opinion of a critical judge sulphur dioxide in the concentration caused by the two lead smelters is not injurious to either animal or vegetable growth, even in their neighborhood.

From a large number of determinations made by the Bureau of Mines it is shown that the sulphur dioxide in the air in Salt Lake City is the result of the combustion of soft coal on the spot. Even at worst the concentration of sulphur dioxide is at no time large enough to be an important factor.

The most interesting feature of this investigation, however, was an experiment made to test the theory that a blanket of sulphurous gas existed over the city. To determine this point analyses of upper strata of the atmosphere were made by the aid of an aeroplane. It was necessary to modify the standardized analytical procedure owing to lack of room for the apparatus and opportunity for its manipulation. Consequently samples of air were taken in the following manner:

Six brown glass bottles of 8 l. capacity were employed. These were charged immediately before the flight with 100 c.c. of a starch solution colored with iodine, and corked with rubber stoppers containing a glass tube closed by a rubber tube and pinch cock. The bottles were then evacuated to a pressure of one inch of mercury, and the pinch cock closed.

Trouble was encountered due to unequal decolorization of the starch solution, but this was eliminated after a thorough cleaning of the bottles and after a strong blue starch solution had been kept in the bottles with frequent shaking for several days.

These bottles were then fixed to the aeroplane fuselage and flight made on a cloudy day when wind was blowing directly from the Garfield smelter. The top of the smoke cloud at that time was about 2,000 ft. above the city. Three samples of air were taken, the first at an elevation of 2,200 ft., the second at 3,000 ft. and the third on the descent at 1,000 ft. Sulphur dioxide was

found in only one sample; at 2,200 ft. the air contained 0.2 part per million.

This meager data serves to substantiate the reasonable prepossession that no heavy blanket of sulphur smoke of high concentration was hanging over the city—at least at any level below 3,000 ft.! The day was typically smoky and undoubtedly conditions were not radically different from the other smoky days during that winter, consequently G. St. John Perrott of the Bureau of Mines' staff absolves the smelters from complicity and ascribes smoke conditions in Salt Lake City to combustion of industrial and residential fuel.

Golden Ejects Bureau of Mines Station

Those interested in the activities of the Bureau of Mines, especially the work in rare metals and the most excellent results in radium and radio-active metals achieved by its personnel in Colorado, will be surprised to know that this station now finds itself homeless as a result of precipitate action by authorities at the School of Mines.

It will be recalled that several years ago, the Bureau's activities were not as widely scattered as at present; in fact, when the Colorado Station was organized in 1910, it was one of the first four, the others being at Pittsburgh, Urbana and Salt Lake City. For five years it was housed in the Foster Building, Denver, and under the direction of Dr. R. B. Moore, now chief chemist of the Bureau, prosecuted very successful work on radio-activity and other problems.

In 1915 the Board of Trustees of the State School of Mines offered the Bureau the free and exclusive use of a three-story building on their campus known as the Engineering Building, but which had housed the department of physics for many years, and consequently possessed many conveniences and advantages which the Denver quarters lacked. A contract was negotiated between the parties, to be renewed year by year, confirming the arrangement, and the Bureau moved its equipment and personnel to Golden. At that time the School was being directed by a group of men who were actively interested in rehabilitating its lost prestige, and were hopeful that their faculty could engage in co-operative investigations with the Bureau's staff of scientists.

Unfortunately this ambition was never realized. In fact the present management of the school apparently is insensible to any advantage of the mutual association, since on June 11 they notified Superintendent S. C. Lind, that they declined to renew the contract expiring July 1 for the Engineering Building, offering instead space in the Experimental Mill, a corrugated iron building equipped as a concentrator, and obviously quite inadequate for the work being done at Golden.

Whereas it has not been definitely decided where the Colorado station will be moved, it is very probable that it will go to Reno, Nevada. The State University has offered to construct a building for such a station, and it should be as well situated as Golden for the prosecution of the special activities intrusted to it.

Properties and Constitution of Glues and Gelatines—I

A Study of Factors Influencing Viscosity and Jell Strength—Effect of Time, Mechanical Treatment, Heating and Dehydration—Influence of Concentration, Temperature and Added Substances

BY ROBERT H. BOGUE, *PH.D.*

GLUES and gelatines† belong to that class of emulsoid protein-like substances which have been a Mecca for hypotheses and speculations to the colloid enthusiast, but a constant source of trouble and embarrassment to the analytical chemist who encounters them. Their place among the emulsoid colloids stamps their physical properties as vague and ill-defined, and pronouncedly variable with slight alterations in the conditions under which the measurements are taken. And their protein-like nature at once assigns to them that complexity of constitution which is today, as it has always been, one of the most intricate and still unanswered problems which the chemist has set himself to solve.

A few publications have appeared from time to time upon the subject in one or another of its many phases, and a few books have long been upon our shelves which have treated very briefly of the chemical and chemico-physical aspects of glues and gelatines; but, on the whole, the subject has not received a great deal of systematic attention. True, the colloid chemist has demonstrated many of his most striking colloid phenomena with gelatine, and the protein chemist has isolated many amino-acids and polypeptides from the hydrolysate of gelatine, but in both of the above cases the examination of gelatine has been merely incidental to their main problem. Manufacturers are still depending in large measure upon the "rule-of-thumb" method in production, and what advance has been made has resulted from the inevitable and costly teacher "Experience," rather than from systematic research.

This series of investigations is an attempt to correlate some of the factors upon which physical measurements depend; to systematize methods for physical and chemical examination; and to discover the relations which exist between the physical constants and the chemical constitution of glues and gelatines.

For convenience the report upon these investigations is divided into sections as follows:

1. Study of Factors Influencing Viscosity and Jell Strength.

2. The Effect of Electrolytes Upon Degree of Dispersion; and the Structure of Gelatine Sols.

This paper presents the results of a part of the work done during the author's incumbency of the Armour Glue Works' Industrial Fellowships Nos. 4, 5 and 6 (1917-1920), at the Mellon Institute of Industrial Research of the University of Pittsburgh. The investigation was carried out with the collaboration of J. R. Powell, chemist of the Armour Glue & Soap Works, and the administration of the Mellon Institute. The author is especially indebted to the late Dr. David S. Pratt, and to W. A. Hamor and E. R. Weidlein. The research is still in progress, and the conclusions presented in this paper will be elaborated and extended in future reports.

*Industrial Fellow of the Mellon Institute of Industrial Research of the University of Pittsburgh.

†The word "gelatine" throughout this series of articles is used when reference is made to the commercial substance, and the word "gelatin" is employed when the protein of that name is under discussion.

A résumé of a part of this report was presented before the American Section of the Society of Chemical Industry, New York, May 21, 1920.

The Relation of Melting Point to Viscosity and Jell Strength.

Relations Between Physical Properties and Chemical Constitution.

Influence of Size of Molecule Upon Physical Constants.

The Physical and Chemical Significance of "Craze," On Chemical Constitution by Determination of the Groups Characteristic of the Amino Acids.

A Study of Adhesive Properties.

Bibliography.

A STUDY OF THE FACTORS INFLUENCING VISCOSITY AND JELL STRENGTH

This section deals with a number of preliminary experiments which have as their object the determination of the effects produced upon the viscosity and jell strength of glues and gelatines by a variation in the conditions under which these measurements are taken. That these effects may be of importance has long been recognized, but the exact extent of their influence under varying conditions has not been thoroughly investigated. While no pretense is made of an exhaustion of the subject in this paper, a few of the important factors influencing viscosity and jell strength have been studied and are presented herewith. The factors considered are: time, mechanical treatment, heat treatment and dehydration, concentration, temperature, and added substances. These latter include formaldehyde, alcohols and non-electrolytes, alums, acids, bases and salts. The influence of these added substances are likewise examined under varying conditions of concentration, time, mechanical treatment, temperature and dehydration.

The results obtained are summarized at the conclusion of each section. An interpretation of the experimental findings will be considered in subsequent papers in this series of articles.

EFFECT OF TIME

The influence of time as a factor affecting the viscosity of glues was noted by running hide glues and bone

TABLE I. EFFECT OF TIME ON VISCOSITY*
* Concentration, 30 g glue to 150 g water Temperature, 60 deg. C.

Time Interval, Min.	Glue H.	Glue B.
0	48.6	45.0
10	48.8	44.8
20	48.8	45.2
30	49.4	46.0
40	48.6	45.6
50	48.4	45.0
60	48.8	45.2
70	48.2	45.0
80	48.0	44.4
90	48.2	45.2

*Grades are specified as follows: H refers to hide glues and fleshing stock. B refers to bone glues. Sub-numerals from 1 to 9 indicate relative order of the strength of their jellies, 1 being the strongest, 9 the weakest.

glues through the viscosimeter* at 10-min. intervals for 90 min. At the temperature at which these measurements are carried out (60 deg.), there is no appreciable change in viscosity with time. This agrees with measurements made by von Schroeder² and Levites,³ who find, however, that at the low temperatures of 21 deg. and 25 deg. the viscosity increases with time.

EFFECT OF MECHANICAL TREATMENT

The effect of mechanical treatment was noted by subjecting glues to different kinds of agitation for different periods of time. Vigorous agitation in each case lowered the viscosity. This agrees with results obtained by Biltz and von Vegesack.⁴

TABLE II. EFFECT OF AGITATION ON VISCOSITY

Glue H ₂	Concentration, 30 g. glue to 150 g. water. Stirred with Rod, 1 Min.	Stirred with Mechanical Beater 4 Min.	Temperature, 60 Deg. Stirred with Mechanical Beater 2 Min.
50.0	50.2	49.0	48.8

EFFECT OF HEAT TREATMENT AND DEHYDRATION

To determine if there were any relation between the moisture content of glues and their physical properties, glues were subjected to partial and complete dehydration by heating at 110 deg. C. for different intervals of time. The loss in moisture was noted after each heat treatment, from which was calculated its remaining moisture content, and the viscosity, jell strength, solubility in cold water and solubility in hot water determined. No uniform variation in these properties could be noted until the glues had been heated for 15 hr., at which time the moisture content had fallen to zero and the resulting glues become "insoluble." The solubility of these "insoluble" glues in cold water was noted to be greater than before this "insoluble" state was reached. The term "insoluble" is here used to mean that condition at which the glue will no longer form a

TABLE III. EFFECT OF DEHYDRATION ON PHYSICAL PROPERTIES

Time Heated in Hr.	Moisture Content	Viscosity	Jell Strength	Solubility in Cold Water	Solubility in Hot Water
0	11.72	51.0	79	6.12	Soluble
1	5.87	51.4	79	6.28	Soluble

homogeneous emulsoid in hot water, after proper soaking in cold water.

This insoluble phase is spoken of in the literature as a reversion of the gelatin to collagen, and Hofmeister⁵ considers collagen the anhydride of gelatin. He writes the equation:

*The instrument used consisted of a glass tube 4 cm. in diameter and 30 cm. long, from which the liquid issued by a capillary orifice. It was standardized to pass 180 g. of water at 60 deg. C. in 48 sec. The time is noted by a stop watch, and the viscosity expressed in seconds.

²Z. physik. Chem., vol. 45 (1903), p. 75.

³Kolloid Z., vol. 2, (1908), p. 240.

⁴Z. physik. Chem., vol. 73 (1910), p. 481.

⁵Jell strength is measured by allowing a blunt inverted cone-shaped weight to rest upon the jelly in a glass tumbler, after chilling at about 10 deg. C. The depression is measured on a graduated scale.

⁶See "Allen's Commercial Organic Analyses," 4th ed. (1913), vol. 2, p. 586.

To test this point, the insoluble phase was treated as an original ossein by soaking in lime-water for several days, and after this treatment heating for some time. A portion left in milk of lime dissolved completely, even in the cold, after ten days. A portion treated with clear lime-water remained firm. This was washed with acid and heated to 70 deg. Solution did not occur readily, but after prolonged heating most of the mass had been dissolved. This seems to be a confirmation of Hofmeister's conclusions.

The effect of prolonged heating on a solution of gelatin was found by Amon,⁶ von Schroeder² and Levites³ to produce a marked decrease in viscosity.

INFLUENCE OF CONCENTRATION

The influence of concentration on the viscosity and jell strength was shown by running the entire list of standard glues through the viscosimeter at four different concentrations, and allowing these solutions to set for jell strength measurements. In all cases the viscosity increases with the concentration, slowly at the lower concentrations but very rapidly at the higher values.

INFLUENCE OF TEMPERATURE

The influence of temperature on the viscosity was shown by running glues at 5 deg. temperature intervals between 30 and 75 deg. The results show a regular increase in viscosity with decrease in temperature. The graph does not, however, show a straight line, for the viscosity increases slowly at high temperature and becomes rapid as the temperature falls toward the jelling point of the glue.

TABLE V. INFLUENCE OF TEMPERATURE ON VISCOSITY

Temperature, Deg. C.	Viscosity in Order of Decreasing Temperature, H ₄	Viscosity in Order of Increasing Temperature, H ₄	Viscosity, H ₄	Viscosity, H ₅

INFLUENCE OF ADDED SUBSTANCES VARYING CONCENTRATION OF FORMALDEHYDE

Runs for viscosity were made with the entire set of standard glues to which were added amounts of formaldehyde varying from 0.8 to 40.0 c.c. of 10.0 per cent solution. This entire series was repeated four times,

*Unpublished investigation conducted at Mellon Institute.

²Z. physik. Chem., vol. 48, (1903), p. 75.

³Kolloid Z., vol. 2 (1908), p. 240.

with varying concentrations of glue; e.g., 10, 20, 30 and 40 g. of glue to 180 g. total weight of solution.

The results may be summarized as follows:

The viscosity varies directly as the amount of formaldehyde added.

After the addition of a certain amount of formaldehyde, the glue sets rather suddenly to a jelly which may not again be brought into solution by the usual means.

The transitional stages between the time when a glue shows only a moderate viscosity and when its viscosity has become too high to measure in the tube may be very short, especially in the weaker concentrations; so short that even in the time it takes to make the test the glue may have changed from a solution of watery consistency to a jelly.

The effect of formaldehyde on viscosity varies very considerably with the different grades of glue, much

hyde as above, to chill at 35 to 40 deg. F. and jell strength observed.

In the higher concentration of glue, the formaldehyde induced the formation of a hard crust on the surface, often harshly wrinkled, which rendered the readings on such samples quite valueless. In the lower concentrations, however, this effect was not pronounced, and the readings are reliable. The results may be summarized as follows:

The jell strength diminishes regularly as the amount of formaldehyde added increases.

This decrease in jell strength is most marked in the weaker glues, which often would not jell at all after the addition of but a few c.c. of formaldehyde.

The results of formaldehyde treatment on the jell strength of Glue H, are expressed graphically in Fig. 2.

The effect of formaldehyde on the jell strength was noted by allowing solutions of all grades of glue in four different concentrations, and containing formalde-

The "formaldehyde capacity" of all of the standard glues at working concentrations was also determined. By "formaldehyde capacity" is meant the maximum amount of formaldehyde which a glue at that concentration may contain without producing insolubility. The

FIG. 2 THE EFFECT OF FORMALDEHYDE ON
JELL STRENGTH

glues were made up in concentrations of from 1 to 2½ up to 1 to 1 and small amounts of formaldehyde added. These were then watched constantly for 2 hr., and the time required to produce insolubility noted.

The general tendency toward a greater formaldehyde capacity in the weaker glues is clearly evident from the data obtained and shown in Table VIII, and expressed graphically in Fig. 3. This formaldehyde capacity is

undoubtedly a function of the chemical composition, the amount of formaldehyde required for precipitation being inversely proportional to, for example, the protein present in the glue.

VARYING CONCENTRATION OF GLUE

The effect of varying the concentration of the glue may readily be observed by selecting a given amount of formaldehyde to be added and noting the effect of this amount on varying concentrations of glue. When this is done, it will be observed that the effect of the formaldehyde becomes felt at much lower concentrations in the high-grade glues than in the low-grade glues.

FIG. 4. THE EFFECT OF TIME UPON THE VISCOSITY OF FORMALDEHYDE-TREATED GLUES

INFLUENCE OF TIME

The influence of time on the effect of formaldehyde on glue was shown by treating two glues with varying amounts of formaldehyde and noting the viscosity at 5-min. intervals for 90 min.; or until set. The results show viscosities increasing with time, slowly at first,

but becoming very rapid as the point of setting is approached. The rate of increase is much greater in the high-grade than in the low-grade glues, and much more rapid with the higher than with the lower concentrations of formaldehyde.

These results are expressed graphically in Fig. 4.

INFLUENCE OF MECHANICAL TREATMENT

The effect of agitation on the viscosity of formaldehyde-treated glues was noted by subjecting glues to which varying amounts of formaldehyde had been added, to different kinds of agitation and noting its effect on the viscosity.

Although the actual viscosity after the treatment was greater in most instances than before treatment, yet, when this increase is compared to the increase noted in a glue treated similarly with formaldehyde but not agitated, it is found to be less than normal. This lessening in the rate of increase is, however, no greater than the actual decrease observed in an untreated glue on similar agitation. It is concluded, therefore, that the effect of agitation on the viscosity of a formaldehyde glue is relatively to decrease it, although the increase due to the time factor is so great as to reverse the actual readings, an actual increase being observed.

INFLUENCE OF TEMPERATURE

The influence of temperature on the viscosity of formaldehyde glues was shown by treating glues with varying amounts of formaldehyde, after the desired

TABLE XI. EFFECT OF AGITATION ON VISCOSITY OF FORMALDEHYDE GLUES

Concentration, 30 g glue to 180 g total				Temperature, 60 deg C.		
C c of 10 per Cent HCHO added	Glue H ₁			Glue B ₂

Beaten two minutes	48 8	52 2	58 0	74 0	45 0	48 6

temperature has been reached, allowing to stand at that temperature for 15 min., and then taking the viscosity. The time factor is thus entirely eliminated.

A study of the results shows in all cases first a drop in viscosity with rise of temperature. When the curves

FIG. 5. THE EFFECT OF TEMPERATURE UPON THE VISCOSITY OF FORMALDEHYDE-TREATED GLUE

are plotted in such a way as to eliminate the influence of the temperature on the untreated glue, it will be seen that the formaldehyde has the least effect at a temperature of 40 deg. C. Below and above this temperature the effect is very pronounced. The effect of a few degrees variation in temperature becomes more and more decided as the amount of formaldehyde is increased, and the range through which the resulting mixture remains mobile is considerably narrowed. It is evident that if it is desired to work a high formaldehyde

glue the optimum temperature of 40 deg. should be selected.

TABLE XII. INFLUENCE OF TEMPERATURE ON VISCOSITY OF FORMALDEHYDE GLUES

These results are expressed graphically in Fig. 5.

EFFECT OF DRYING ON VISCOSITY AND SOLUBILITY

To determine the permanent effect which formaldehyde might have on a glue, the glue H₁ was treated in two concentrations with varying amounts of formaldehyde. The viscosity was taken after 15 min., the glues then dried and, after drying, were again brought into solution, if possible, and the viscosity taken.

It is seen that the viscosity of the samples after treatment is greater in all cases than that of the original solutions. This increase is proportional to the volume of the formaldehyde used and to the concentration of

TABLE XIII. EFFECT OF DRYING ON VISCOSITY AND SOLUBILITY OF FORMALDEHYDE GLUES

Glue H ₁ Temperature 60 Deg C		Time, 15 Min		40 g Glue to 180 g

Viscosity after drying	49 0	53 2	56 0	75 2	Insol
				65 0	Insol

the glue. It seems probable that the mere physical process of drying alone has no influence on the viscosity, but rather that the change noted is a function of the time factor alone.

ALCOHOLS AND NON-ELECTROLYTES

The influence of three alcohols on viscosity was tested. Methyl, ethyl and amyl alcohols were added to glues H₁, H₂ and B₂ and allowed to act for 15 and 90 min. after which time intervals the viscosities were taken.

In all cases the viscosity is increased above that of the untreated samples. This increase diminishes, however, with time. An excess of the methyl and ethyl alcohols produces insolubility by precipitation of the proteins. These were not precipitated by the amyl alcohol, but a persistent white crust as of a crystallizing salt formed on the surface.

The influence of chloral hydrate on viscosity and jelly strength was studied. This substance was added to glues H₁ and H₂ in amounts varying from 1.0 to 30.0 per cent. Its influence was very marked. It was found to increase the viscosity very considerably and to lower the jelly strength until the mixture would no longer tell

at 5 deg. C. The increase in viscosity was found to continue regularly even after such concentrations had been added that the solution would not jell.

50	Set	76	Set	75	56.8	79

solution could not be effected with larger amounts than 20 c.c.

The alums all produced increases in viscosity much

the same as the formaldehyde had done except that a much larger amount of the former had to be added in order to obtain the same degree of increase. The chrome alum showed much the greatest effect of the three, producing insolubility when only 15 c.c. had been added, as against 50 c.c. of the aluminum alum.

The influence of these substances on the jell strength does not seem to be appreciable.

These results are expressed graphically in Fig. 6.

INFLUENCE OF TIME AND OF TEMPERATURE

The influence of time on the viscosity of alum glues was noted by adding different amounts of the alums to the glues, and measuring the viscosity at intervals up to 80 min.

The data reveal the fact that the influence of time on the viscosity of alum glues is exactly opposite to its influence on formaldehyde glues. Whereas with the latter the viscosity rapidly increases from a condition of watery consistency to its setting point, the alum glues, on the other hand, develop their maximum viscosity very quickly, after which, however, it rapidly decreases with time to a low value, approaching that of the untreated glue.

TABLE XVII. EFFECT OF TIME ON VISCOSITY OF ALUM GLUES

Glue H₂, Concentration, 30 g. glue to 180 g. total weight. Temperature 60 Deg. C.

Time Interval in Min.	Al (N/10)		Cr (N/10)	
	0 c.c.	40 c.c.	10 c.c.	12 c.c.
1	49.2	56.4	66.4	135.0
2	49.2	280.0	68.4	144.2

70	49.2	61.6	55.6	72.4
80	49.2	61.6	56.2	73.0

These results are expressed graphically in Fig. 7.

The influence of temperature on the viscosity of alum glues was noted by treating glues with different amounts of alum solutions, after heating to the desired temperature, and allowing to stand at that temperature for

FIG. 7. THE EFFECT OF TIME UPON THE VISCOSITY OF ALUM-TREATED GLUES

15 min. The viscosities were then taken. Temperature intervals of 10 deg. were used between 30 and 70 deg. C.

The data show the effect of varying temperature on the viscosity of alum glues to be likewise different from its effect on formaldehyde glues. Between 30 and 40 deg. the effect is the same, e.g., a lowering in viscosity, but above 40 deg. the alum glues continue

FIG. 8. THE EFFECT OF TEMPERATURE UPON THE VISCOSITY OF ALUM-TREATED GLUES

regularly to decrease in viscosity, whereas in the formaldehyde glues it rises rapidly from that temperature.

From the above experiments, it would seem that although both alums and formaldehyde may produce insolubility in glues and increase their viscosity, in proportion to the amount used, yet, inasmuch as the effects of time and temperature are so different in the two cases, the physical or chemical mechanism of the processes is undoubtedly quite different.

70	53.0	69.2	60.0	91.2

These results are expressed graphically in Fig. 8.

ACIDS, BASES AND SALTS

The influence of acids, bases and salts on viscosity and jell strength has been tested in a number of ways. Several salts, acids and bases were added to nine different glues in varying concentrations from 0.1 to 30.0 per cent and the viscosities and jell strengths noted.

The results obtained may be summarized as follows:

Practically all of the substances added lowered the jell strength.

Strong (9N) sodium hydrate had the greatest effect, followed by potassium iodide, strong (9N) sulphuric acid, sodium sulphate, acetic acid and magnesium chloride. The effect of the others was small.

The viscosity was raised constantly by magnesium chloride, chloral hydrate and sodium silicate.

The viscosity was raised to a maximum, after which, it fell more or less rapidly by sodium hydrate, disodium phosphate and acetic acid.

The viscosity was lowered constantly by potassium iodide, sulphuric acid, phosphoric acid and sodium sulphate.

There was no appreciable effect on the viscosity due to sodium chloride and magnesium sulphate.

Monosodium phosphate produced a sharp drop of one second at 0.1 per cent, followed by a sharp rise of 3½ sec. at 0.5 per cent, after which it rose a little further and then dropped again.

A part of the data for glue AA which is typical of the whole series is given in Table XIX, and is expressed graphically in Figs. 9 and 10.

FIG. 9. THE EFFECT OF ADDED SUBSTANCES UPON JELL STRENGTH

The experimental findings which have been presented in this chapter may be briefly summarized as follows: There is no variation in the viscosity of normal glues with time up to 90 min.

Vigorous agitation of a glue or gelatine results in a lowering of the viscosity.

Prolonged heating results in a decrease in viscosity.

Dehydration produces a reversion of "soluble" gelatine to "insoluble" collagen.

FIG 10 THE EFFECT OF ADDED SUBSTANCES UPON VISCOSITY

At temperatures well above the melting point the viscosity increases nearly as a logarithmic function of the concentration.

The viscosity varies inversely as the temperature.

The viscosity varies directly as the amount of formaldehyde added. The higher the grade of a glue, and the higher the concentration, the less the amount of formaldehyde required to produce "insolubility."

The jell strength varies inversely as the amount of formaldehyde added. This effect is the more marked in the weaker grades of glue, and in the lower concentrations.

The viscosity of formaldehyde-treated glues increases with the time.

The viscosity of formaldehyde-treated glues decreases with rise in temperature up to about 40 deg. C. Above this temperature the viscosity rapidly increases to the setting point.

The addition of chloral hydrate results in a continually increasing viscosity, and a continually decreasing jell strength.

Alums produce increasing viscosities, but have little or no effect upon jell strength.

The viscosity of alum-treated glues increases very rapidly with time for a few minutes, after which maximum it decreases slowly.

The viscosity of alum-treated glues decreases regularly with rise in temperature.

Nearly all electrolytes produce a lowering in the jell strength, but their effect upon viscosity may be continually to increase, continually to decrease, or first to increase and later to decrease the viscosity.

(Part II will appear in a subsequent issue.)

Utilization of British Water Powers

The report of the British Government Water Power Resources Committee (which will shortly be published) sets forth a scheme for the utilization of the water power of the United Kingdom in place of coal and oil. The committee's task was to consider the extent to which the water power in rivers can be made available as power for industry, and to advise on the steps to be taken to insure that the water resources are properly conserved and fully utilized for all purposes.

The chief recommendation is the creation of a body of water commissioners as a department of the Board of Trade, with general authority to see that the water power in the country is utilized to the best advantage. These commissioners would have functions similar to the electricity commissioners already appointed, and would be able to approve local schemes for the development of the water supply without the reference to Parliament now necessary. They would also encourage the promotion of local schemes and prevent wasteful competition between local authorities for water supplies.

An important recommendation of the forthcoming report is that where one authority has more water than it requires it should be compelled to supply it to a less favored district at a reasonable cost. The committee has mapped out the whole of England and Wales into districts as they are served by different watersheds, and suggests the creation of local committees in counties and groups of counties to arrange for the best use of the water supply in those districts.

Market for American Dyes in Burma

The few consignments of American dyes that have arrived in Burma are reported so satisfactory in quality that importers have signified their desire to receive more, especially of those adapted to dyeing silks, as the supplies of the native cotton-dyeing works are obtained from India. The colors most in demand are pink (three shades), green, blue, first red, scarlet, orange, lemon, yellow, violet, black, and blue-black. Dyes for this market should be put up in 1-oz., 7-oz., and 1-lb. tins, wrapped in labels showing the color, and packed in tin- or zinc-lined cases, as the usual paper wrappings are worthless in this climate. The smaller sized tins have the readier sale. Aniline dyes pay an import duty of 7½ per cent ad valorem upon the fixed tariff valuation of 2 rupees per pound moist, and four rupees per pound dry.

Alberta May Resume Sugar-Beet Raising

The present high price and scarcity of cane sugar have led J. A. Grant, British Columbia Fruit Commissioner, with headquarters in Calgary, Alta., to declare that resumption of sugar beet growing is necessary to prevent extreme shortage.

Sugar beets were formerly grown successfully in Alberta and a factory was operated at Raymond, but at that time competition with cane sugar, which sold at 8c. and 10c. per lb. was too keen and the industry was abandoned.

At the present price of cane sugar, it is estimated that beet sugar can be produced at a profit in competition with it, and already commercial interests are seriously considering entering this field. Mr. Grant is quoted as saying that beet sugar can be produced in Alberta at 10c. a lb.

The Heat Treatment of a High-Chromium Steel

A Study of the Relation of Various Heat Treatments on the Physical Properties and Microscopic Appearance of Stainless Steel — Comparatively High-Temperature Annealing Is Required to Alter the Structure of the Hardened Material

By H. J. FRENCH* AND YOSHITO YAMAUCHI†

HIGH-CHROMIUM steel containing about 11 to 15 per cent of chromium and usually 0.20 to 0.40 per cent of carbon is manufactured under the name of "Stainless Steel," because of its peculiar property, when properly hardened and finished, of resisting oxidation and corrosion by the ordinary agents.

Originally employed in the manufacture of cutlery, such steel has proved its value in other fields and gives promise of wider application. It has been successfully used to replace high-nickel and high-speed steels for valves in airplane and automobile engines and will probably receive attention for other machine parts subjected to corrosive action or oxidizing service conditions.

One of its main disadvantages is its high chromium content, which makes it a costly alloy. It is also quite sensitive to mechanical and thermal treatments, but combines high strength and good ductility with its ability to resist corrosion, which is a combination difficult to duplicate.

While chromium was one of the first of the steel-alloying elements, its use was for many years confined to high-carbon products due to the difficulty of manufacturing carbon-free chromium. So-called "Stainless Steel" is, therefore, one of the indirect results of improvements in the manufacture of carbon-free ferro-alloys.

PREVIOUS INVESTIGATIONS

Comparatively little information has been published concerning the physical properties of "Stainless Steel." In 1917, W. H. Hatfield¹ published results of tensile and impact tests of a steel containing 0.30 per cent carbon and 13.0 per cent chromium. A comparison between air, oil and water quenching followed by relatively high temperature tempering is given. His tensile test results have also been incorporated in the tentative report of the Iron and Steel Committee of the Society of Automotive Engineers² and constitute the major portion of the physical test data there given. The latter report, however, includes a valuable and interesting discussion of the proper methods of working, annealing and finishing such steel and a comparison between stainless, high-speed and some commonly used structural alloy steels, in resistance to oxidation at high temperatures.

A rather complete discussion of the properties of stainless steel is given by Seidell and Horvitz in *Iron Age*.³ The work of previous investigators on high-chromium steels of varying carbon content is reviewed, and typical differential heating and cooling curves are

given for a steel containing 0.33 per cent carbon and 11.02 per cent chromium. The authors clearly show the suppression of the ferrite transformation together with the lowering of the A₁ transformation as maximum heating temperature is increased. Brinell hardness values under varying quenching and temperature treatments and relation to so-called "red-hardness" are also shown. Little data are given, however, on the tensile properties.

MATERIAL USED

In order to determine the effect of various heat treatments on the tensile properties of such high-chromium steel and throw further light on its possible use for various machine parts, a series of tests has been carried out on two bars of annealed 1-in. hot-rolled rounds of the following composition:

	Ladle Per Cent	Checks Per Cent
Carbon	0.27	0.29 (0.24)
Manganese	52	38 (0.36)
Phosphorus	0.11	0.09
Sulphur	0.09	0.15
Silicon	0.95	70
Chromium	12.4	13.2 (13.2)

In the annealed condition, as supplied, the steel showed the following tensile properties, in which condition it machines quite readily:

Proportional limit, lb. per sq. in.	64,000
Tensile strength, lb. per sq. in.	106,900
Elongation in 2 in., per cent	26.0
Reduction in area, per cent	58.5
Brinell hardness number	222
Shore hardness number	34

METHODS USED

All treatments were carried out on standard Zimmer-scheid tensile test specimens, the gage length being left 1/2 in. larger than the specified diameter (0.505 in.) for grinding after heat treatment. The effective diameter in treatment was, therefore, 3/4 in. For hardening, samples were heated in gas-fired furnaces, while for tempering, an oil bath was used at 400 deg. F. (205 deg. C.), a 2 to 1 mixture of sodium and potassium nitrates at 800 and 1,000 deg. F. (427 and 538 deg. C.) and a Hoskin's electric muffle furnace at 1,200 deg. F. (649 deg. C.). All temperatures up to and including 2,100 deg. F. (1,149 deg. C.) were measured by standardized 14-gage chromel-alumel couples connected to a Leeds & Northrup potentiometer. Quenching from 2,250 deg. F. (1,233 deg. C.) was controlled by a Leeds & Northrup optical pyrometer.

All tensile tests were made on a 100,000-lb. Riehle testing machine. Proportional limits were obtained from stress-strain diagrams, the deformation being taken with an extensometer reading to 0.002 in. Brinell hardness values were obtained under standard conditions (3,000 kg. load on a 10 mm. ball \pm 0.025 mm.) using an alpha machine, and a recording scleroscope was used for Shore hardness.

THERMAL ANALYSIS

Before carrying out the various thermal treatments heating and cooling curves were taken with the modified Rosenhain type furnace in use at the Bureau of Standards, a description of which will be found in the August, 1919, *Bulletin of the American Institute of Mining and Metallurgical Engineers*.³ The inverse-rate curves ob-

FIG 1 EFFECT OF VARYING QUENCHING TEMPERATURES

tained showed discontinuities with rising temperature at 700 and 870 deg. C., and on cooling at 800 and 700 deg. C. (approximately).

VARYING QUENCHING TEMPERATURES

The effects on tensile properties and hardness of varying the oil-quenching temperature are shown in Fig. 1, based on experimental results. For the temperatures chosen interesting features are noted:

(a) The best combination of strength and ductility is obtained in quenching from 1,750 deg. F. (953 deg. C.), which condition is coincident with maximum tensile strength.

(b) Maximum hardness and maximum strength do not coincide.

(c) Ductility, as measured by both elongation and reduction, decreases rapidly as quenching temperature is increased. It reaches a very low value at 1,850 deg. F. (1,010 deg. C.), above which temperature it remains practically constant. This decrease in ductility and also increase in grain size with increase in oil-quenching temperature is clearly indicated in fractures obtained in tensile tests, as shown in Fig. 2.

(d) Minimum ductility, as measured by both elongation and reduction, does not correspond to maximum tensile strength or proportional limit.

(e) Proportional limit is a difficult factor to determine in cases where ductility is low, its exact value largely depending upon the observer. A typical stress-strain diagram shows marked resemblance to a curved line.

VARYING TEMPERING TEMPERATURE

The effect of varying tempering temperature up to about 1,200 deg. F. (649 deg. C.) on samples previously

FIG. 2. FRACTURES OF QUENCHED BARS

FIG 3. EFFECT OF DIFFERENT ANNEALS ON STAINLESS STEEL QUENCHED FROM 1,750 DEG. F.

quenched from 1,750 deg. F. (953 deg. C.) and 2,100 deg. F. (1,149 deg. C.) is shown in Figs. 3 and 4. It is interesting to note that the strength of this steel is not lowered upon tempering for short periods of time until a temperature in the neighborhood of 800 deg. F. (427 deg. C.) is reached. Between 800 deg. F. (427 deg. C.) and 1,000 deg. F. (538 deg. C.) a marked decrease in strength and increase in ductility are obtained.

The inherent brittleness of those samples quenched from the higher temperatures probably accounts for the marked increase in tensile strength with increase in tempering temperature up to 800 deg. F. (427 deg. C.) on those samples quenched from 2,100 deg. F. (1,142 deg. C.), as shown in Fig. 4. Short time tempering gradually relieves the initial stresses set up in quenching until at about 800 deg. F. (427 deg. C.) these are

FIG 4. EFFECT OF DIFFERENT ANNEALS ON STAINLESS STEEL QUENCHED FROM 2,100 DEG. F.

overcome to such an extent as to allow the material to develop its maximum resistance to static tensile stress. Evidence of brittleness but to a smaller degree in those samples quenched from 1,750 deg. F. (953 deg. C.) is likewise clearly shown by the shape of the tensile

strength curve in the range of low tempering temperatures (Fig. 8).

It is possible that the low tensile strength of these hard specimens is affected somewhat by the conditions of heating.

If the specimens are not perfectly straight, the stress applied in the testing machine is not parallel to the

FIG. 5 HARDNESS QUENCHED DISKS, 1 IN DIAMETER, 1/4 IN THICK

axes of the specimen and as the material has low ductility it cannot adjust itself and so breaks at a value lower than the true tensile strength. However, as all test specimens were ground after heat treatment, this effect has been kept to a minimum.

According to Guillet's constitutional diagram the steel under consideration is in the martensitic range; that is, on normal air-cooling from above the critical ranges only partial transformation of the solid solu-

tion takes place, so that on reaching room temperature martensite remains as the stable constituent. Such steel is referred to as "self-hardening steel," and it is necessary to resort to very slow cooling, as in a furnace, for annealing. Comparison of Brinell hardness values between water, oil and air cooled 6-in. thick, 1-in. disks heated to various temperatures is given in Fig. 5 and clearly indicates that the steel in small sizes will harden equally well in air as in oil or water. In practice furnace cooling from about 1,400 deg. F. (760 deg. C.) to a temperature in the neighborhood of 1,000 deg. F. (538 deg. C.) followed by air-cooling to room temperature is a satisfactory method of annealing. By heating to about 1,750 deg. F. (953 deg. C.) and cooling in a manner similar to the above, the steel is brought into an even softer condition though one not quite as satisfactory for ordinary machining.

Micro-examination of all heat-treated tensile test samples was made, and in some cases reveals interesting structures. For etching the reagent mentioned by Seidell and Horwitz consisting of a mixture of 2 parts of 50 per cent solution of hydrochloric acid, 2 parts of 15 per cent solution of ammonium persulphate and 1 part of concentrated alcoholic solution of o-nitrophenol was at first used. This in general gave satisfactory results, but a mixture of 2 parts of concentrated nitric acid and 1 part of concentrated hydrochloric acid diluted with 3 parts of water was finally adopted as meeting all requirements. With this reagent satisfactory development of structure was obtained by immersion

FIGS. 6 TO 11. MICROSTRUCTURE OF HEAT-TREATED SPECIMENS X 500

Fig. 6—Oil quenched from 1,550 deg. F. Fig. 7—Oil quenched from 1,950 deg. F. Fig. 8—Oil quenched from 2,100 deg. F. Fig. 9—Oil quenched from 1,750 deg. F. Tempered 30 min. at 815 deg. F. Fig. 10—Oil quenched from 1,750 deg. F. Tempered 30 min. at 1,225 deg. F. Fig. 11—Oil quenched from 2,100 deg. F. Tempered 30 min. at 1,000 deg. F.

for from 30 to 90 seconds. Samples quenched from the highest temperatures without subsequent tempering required the longest immersion,* while the remainder required only 30 to 60 seconds. *

All samples oil quenched from above 1,750 deg. F. (955 deg. C.) without subsequent tempering show a martensitic structure as shown in Fig. 6. Above 1,850 deg. F. (1,010 deg. C.) the "needles" become quite large (Fig. 7) and in those samples quenched from 2,100 and 2,250 deg. F. (1,149 and 1,233 deg. C.) there is evidence of retention of the solid solution. Fig. 8 shows a portion of the cross-section of one sample, which in particular exhibits the polygonal structure characteristic of austenite. Partial preservation of these grain boundaries is also evident in a sample quenched from 3,250 deg. F.

Close examination of micrograph 6 and others not shown further reveals minute carbide globules in samples representing the steel as oil quenched from temperatures between 1,562 and 1,750 deg. F. (852 and 955 deg. C.). The steel as quenched from 1,750 deg. F. (955 deg. C.) and 2,100 deg. F. (1,149 deg. C.) and tempered at various temperatures between 400 and 1,235 deg. F. (206 and 668 deg. C.) shows similar features as illustrated in Figs. 9, 10 and 11. Samples quenched from the lower temperature show a partial precipitation of carbide (Fig. 9), while those first quenched from the higher heat are practically free from this constituent until tempered at 1,000 deg. F. (538 deg. C.) or above, but show evidence of retention of polyhedral grain boundaries even when tempered at the higher tempering temperatures used (Fig. 11).

It is interesting to note that the structures* obtained in quenching generally persist even at tempering temperatures fairly close to the critical ranges, a phenomenon which is undoubtedly directly associated with the special properties of this steel.

SUMMARY

Samples of a high-chromium steel quenched in oil from various temperatures show:

(a) That with increasing quenching temperature hardness as measured by Brinell and Shore instruments increases until a temperature of about 1,950 deg. F. (1,066 deg. C.) is reached. Maximum range of hardness is generally obtained by quenching from this temperature up to the highest heat used, but in some cases this hardness actually decreases due to retention of the solid solution.

(b) That quenching from about 1,750 deg. F. (955 deg. C.) develops the best combination of strength and ductility which is not coincident with range of maximum hardness. Quenching from this or lower temperatures does not retain all the carbide in solution as is the case in samples quenched from considerably higher temperatures (notably 2,100 and 2,250 deg. F. (1,149 and 1,232 deg. C.).

(c) That ductility as measured by elongation and reduction is very low in those samples quenched from 1,850 deg. F. (1,010 deg. C.) or above.

Short time tempering at temperatures up to about 800 deg. F. (427 deg. C.) of samples previously quenched from both 1,750 deg. F. (955 deg. C.) and 2,100 deg. F. (1,149 deg. C.) decreases brittleness. However, ductility is increased to a greater extent in those samples quenched from 1,750 deg. F. (955 deg. C.) than in those quenched from the higher temperature.

* Tempering above about 800 deg. F. (427 deg. C.)

markedly decreases strength values and hardness, which is of course accompanied by greatly increased ductility.

In general, the structure of the hardened steel tends to persist even when tempered for a short period of time at temperatures comparatively close to the lower critical range, the characteristics depending upon the quenching temperature used.

The most rapid change in tensile properties and hardness occurs in tempering between about 800 and 1,000 deg. F. (427 and 538 deg. C.).

Effects of Oils and Heat on Glues*

Plywood may be used near machinery and tanks with little likelihood of being dangerously weakened by the action of oil or gasoline on the glue joints. Plywood panels glued with animal, vegetable, blood albumin and casein glues were immersed for nearly a year in engine oil and gasoline. At regular intervals specimens were removed from the liquids and tested for joint strength. All the glues weakened somewhat during the early part of the test, the animal and vegetable glues more than the casein and blood albumin glues. The total loss of strength in any case, however, was small enough to be negligible under most conditions of service. A glue shear strength of 100 to 125 lb. per sq.in. is considered sufficient for practically any purpose for which plywood is used. Only in two or three instances did the strength of the casein and blood albumin glues fall below 150 lb. per sq.in. Engine oil, castor oil and gasoline seemed to have practically the same effect on the glue joints.

During the forty-five weeks' test, the wood absorbed 60 per cent of its original weight in engine oil and 70 per cent of its original weight in gasoline. The absorption of these oils did not cause any noticeable swelling of the wood.

Long-continued heating, however, will reduce the strength of animal glues. Solutions of a high-grade joint glue and a veneer grade glue were heated for forty-eight hours at 104, 140 and 176 deg. F., and tested every few hours during this period for strength and viscosity.

In the first seven hours of heating at 176 deg. the veneer glue lost approximately one-half its joint strength, and the high-grade glue joints weakened almost as much. The greatest loss in the strength of the glue joints occurred at this temperature. In the solutions kept at 104 deg. there was a sudden drop in the strength of the joints made with the high-grade glue after thirty-one hours of heating, due possibly to a combination of bacterial and chemical action. The veneer glue joints showed a more gradual decrease at this temperature. The most favorable of the three temperatures tried was 140 deg., but even at this temperature an appreciable weakening in both glues was noted at the end of seven hours, and longer heating caused greater loss.

The viscosity of the high-grade glues declined more rapidly than that of the veneer glue, but at the end of the heating test the viscosity of the high-grade glue still averages higher than that of the veneer glue.

Covered glue pots were used in this experiment. When open glue pots are used the loss in strength caused by the heat is less apparent, since the loss is compensated to some extent by evaporation of the water. But the concentration of the glue solution through evaporation is an expensive means of gaining strength.

Permeability of Rubber to Gases—I

Nature of Permeability and Methods and Apparatus for Its Determination Described—Effect of Factors: Characteristics of Rubbers Used, Pressure Differences, Sheet Thicknesses, Time and Temperature*

BY JUNIUS D. EDWARDS† AND S. F. PICKERING‡

RUBBER has been in everyday use as a gas-retaining material for a great many years. Nevertheless, until the recent development of the modern rubberized balloon fabric, comparatively little advance was made in our knowledge of the permeability of rubber to gases. With the development of fabrics for lighter-than-air craft came the demand for accurate methods of measuring permeability, together with a demand for the most varied kinds of information regarding the permeability relations of rubber and gases. The Bureau of Standards has already, in its Technologic Paper 113¹ (hereafter referred to as T.P. 113) published the results of an investigation of methods for the determination of the permeability of rubber to hydrogen. Correlated with that work has been the present investigation of the factors involved in the passage of gas through rubber and the permeability of rubber to different gases.

NATURE OF PERMEABILITY PROCESS

Graham² in his classic and pioneer work on the "Dialytic Separation of Gases by Colloid Septa" was the first to point out that the characteristic passage of gas through rubber took place by solution in the rubber and

FIG. 1. DIAGRAM OF STANDARD APPARATUS FOR DETERMINING PERMEABILITY

not by diffusion through microscopic openings. If gases passed through rubber by the process of diffusion as through a porous plate, their rates of penetration should be approximately inversely proportional to their viscosities. As pointed out by Graham, the relative rates of penetration of different gases bear no relation to their densities or their viscosities. In fact, it is difficult to correlate the permeability with any of the well-known properties of the gases. It is quite obvious from a consideration of the facts that some phenomenon other than diffusion through small openings is con-

cerned, and that the properties of both rubber and gas determine the rate of penetration.

METHODS OF DETERMINING PERMEABILITY

The permeability of a rubber film may be defined as the rate at which it is penetrated by a certain gas. Permeability will be expressed in terms of liters of gas per square meter per twenty-four hours, the volume of gas being corrected to the standard conditions of zero deg. C. and 760 mm. mercury pressure. Unless stated otherwise, all determinations are made under the following conditions, which are adopted as standard for this work: The fabric is held at a temperature of 25 deg. C. with air at atmospheric pressure (760 mm. of mercury) on one side of the fabric and the gas in question at an excess pressure of 30 mm. of water on the other side.

DESCRIPTION OF METHODS AND APPARATUS

Most of the different types of apparatus available for the determination of permeability have been described in T.P. 113, to which reference has been made. What may be called the standard apparatus of the Bureau of Standards is shown in diagram in Fig. 1. The rubber sample to be tested is held in the permeability cell *a*, which is maintained at a constant temperature in an air or water bath *h*. The cell consists of two circular plates with a shallow chamber in each. The test piece is held between the flanges of the cell and separates the two chambers; it is supported by a series of crossed wires in the form of a screen. A constant concentration of the gas whose permeability is to be measured is maintained in one chamber. The gas which penetrates the exposed area of rubber passes into the other chamber, from which it is continuously removed by a stream of air or other gas and determined quantitatively.

Because of the common use of hydrogen in balloons, the permeability to hydrogen is the property most often determined in the case of balloon fabrics. For this reason, and because of the accuracy with which the permeability to hydrogen can be determined, the permeability to any other gas will be referred to its permeability to hydrogen as the standard of comparison.

In determining the permeability to hydrogen, a current of pure dry hydrogen is passed over one side of the fabric and out through a water seal. Dry air under carefully regulated pressure is passed over the other side of the fabric, through a drying tube *d*, and into one chamber of a gas interferometer where the percentage of hydrogen in the air is determined optically. The gas then passes out through the drying tube *d*, which prevents diffusion of water vapor into the interferometer, through the saturator *f* filled with glass beads partly covered with water and then through the wet meter *m*. The saturator is employed to prevent loss of water from the meter by evaporation into the gas which

*This paper is a condensation of a comprehensive report to be issued by the U. S. Bureau of Standards.

²Phil. Mag., vol. 22, p. 401; 1866.

is being measured. Arrangements are made for bypassing the air stream from the interferometer to the meter when the interferometer is being read and for supplying the comparison chamber of the interferometer with pure dry air.

The gas interferometer* of the Rayleigh type measures the difference in refractivity of the two samples of gas contained in the gas chambers of the instrument. Several interferometers were used and their sensitivity was such that each scale division indicated from 0.007 to 0.01 per cent hydrogen in air. The average of ten settings of the instrument gave a reading which was good to somewhat better than one scale division; this gives ample precision in the determination of the hydrogen. The calibration of the interferometer, both for hydrogen and other gases, was accomplished by the method described by one of us in the *Journal of the American Chemical Society*.†

CHARACTERISTICS OF RUBBER SAMPLES EMPLOYED

The greater part of the determinations recorded were made with rubber films as they are contained in balloon fabrics. This was done not only because of the immediate application of the results in that field, but also because balloon fabrics of great variety were readily available. Rubber films of satisfactory uniformity and low permeability are also most easily secured in the form of balloon fabrics. The support given the rubber film by the cloth on which it is spread simplifies the handling and testing of the material. The question might be raised as to whether in some cases the results might not be influenced by the cloth on which the rubber is spread. To test this point, determinations were also made on thin sheet rubber in those instances. The absolute permeability of the rubber is profoundly modified by the cloth, as will be shown later; its relative permeability to different gases is apparently not affected thereby.

RELATION OF PERMEABILITY TO COMPOSITION OF RUBBER

For the present purpose rubber may be considered to be a mixture of "polyprene," $(C_2H_3)_x$, in different stages of polymerization, together with resins, nitrogenous matter, water and inorganic material in varying proportions. Vulcanized rubber, which we will hereafter refer to simply as rubber, contains in addition varying proportions of sulphur, combined with or adsorbed by the polyprene together with some free sulphur. Compounding materials in great variety may also be added to the rubber to give it desirable characteristics but where imperviousness to gases is desired their use is usually restricted.

RELATION BETWEEN PERMEABILITY AND COMPOSITION

Without going into the detailed evidence contained in the complete report it may be desirable to summarize some of the observed facts in regard to permeability and composition:

The aging of rubber in thin films is accompanied by a characteristic decrease in permeability.

The aging of rubber is usually accompanied by a decrease in the percentage of total sulphur; the combined

sulphur increases by varying amounts and the free sulphur decreases eventually to a low value.

In one series of fabrics where the degree of cure was varied, no significant change in permeability was observed. In this case the percentage of combined sulphur varied from 0.3 to 2.5 per cent. In another series, large changes in permeability were noted with change in the degree of cure; the combined sulphur varied from 1.6 to 5.0 per cent. The original acetone extract was approximately constant in each series.

Because of the number of factors involved it would be unwise to draw any very extensive conclusions. The view is quite widely held by manufacturers and others that the permeability of a fabric can be reduced by increasing the degree of cure. Between certain limits this is true. That this reduction in permeability is caused entirely by the increase in combined sulphur is not at all certain. Opposed to this latter view is the fact that as great and greater decreases in permeability are noted on fabrics exposed to the weather where there are relatively small changes in combined sulphur. The most striking change in exposed fabrics is the increase in acetone extract, which increase is a measure of the resinification and oxidation of the rubber. It appears reasonable to believe, therefore, that an increase in combined sulphur and acetone extract each cause a decrease in permeability. This would be the natural result if hydrogen was insoluble in both the acetone-soluble material and the "polyprene sulphide."

It has been thought by some that the free sulphur plays an important part in determining the permeability. The free sulphur which is present in the colloidal condition in the rubber after vulcanization frequently crystallizes out. This is strikingly shown by the microsection of a sample of ballonet fabric illustrated in Fig. 2. The sulphur crystals are seen as dark dendritic masses in the rubber between the two plies of cloth. A certain amount of this sulphur eventually penetrates to the surface and evaporates. This process might possibly produce a certain porosity which would increase the permeability. Tests made on portions of the fabric of Fig. 2 where crystallization was extensive showed no significant difference in permeability as compared with portions where crystallization had not occurred. Certainly our tests and experimental methods have not

FIG. 2. MICROSECTION OF BALLONET FABRIC ($\times 135$) SHOWING SULPHUR CRYSTALS

*For detailed description see L. H. Adams, *J. Am. Chem. Soc.*, vol. 37, p. 1,181; 1915.

been of sufficient delicacy to detect any effect on the permeability which can be ascribed to this blooming out of sulphur.

Compounding materials may be added to the rubber either to make it more impervious to gases or to give it greater durability. Paraffine and glue are two substances which are said to lower the permeability of rubber to hydrogen. It is known that either of them alone will give a film of very low permeability providing it is non-porous. Their use is not essential, how-

FIG. 3. RELATION BETWEEN PERMEABILITY AND PARTIAL PRESSURE OF HYDROGEN

ever, to the production of a satisfactory coating for balloon fabrics. Lampblack, zinc oxide, litharge may be incorporated in the rubber to give it greater life by protecting the rubber from the injurious action of light.

RELATION OF PERMEABILITY TO PRESSURE

In considering the effect of pressure, a distinction should be made between the total pressure and the partial pressure of any constituent. A difference in the total pressure on the two sides will produce tension in the rubber film and a change in thickness or physical properties may result. The effect of a change in the total pressure will be influenced by the support given the rubber film such as when it is held between cloth of one or more plies, as in the case of a balloon fabric. The work of previous investigators indicates that the permeability of rubber to any gas is about proportional to the partial pressure of that gas. The agreement on this point is not unanimous, however, and the methods and data recorded are not satisfactory in all particulars.

In Fig. 3 is shown the relation between permeability and difference in partial pressure of hydrogen as shown by tests on six different test pieces of the same fabric. The percentages of hydrogen in the air were determined by means of the interferometer. The permeability of the different test pieces with 100 per cent hydrogen varied from 9.4 to 10.0 liters; each result was therefore multiplied by the ratio of 10 to the observed permeability at 100 per cent so that the 100 per cent value became 10 in each case and all the other values were directly comparable. It may be concluded from these results that the permeability is directly proportional to the partial pressure within the limits of experimental error. Similar results were obtained with carbon dioxide as shown in Fig. 4.

In accordance with the conclusion that the permeability was directly proportional to the partial pressure, the results of all permeability determinations have been corrected to the standard condition of a partial pressure

of 760 mm. in the following manner. For example: In one determination with carbon dioxide (99.9 per cent pure) there was 0.6 per cent carbon dioxide in the air on the opposite side of the fabric; the barometric pressure was 750 mm. and the observed permeability 20.0 liters. The corrected permeability is then equal to

$$20.0 \times \frac{760}{750} \times \frac{100.0}{99.9 - 0.6} = 20.4 \text{ liters.}$$

The change in permeability when the difference in the total pressure on the two sides of the sample is varied follows no simple law. In this case, not only does the permeability change with the change in partial pressure but also it may change with any variation in thickness caused by the tension on the rubber. Obviously the effect will vary with the support given the rubber. In the case of a balloon fabric the rubber film is given very intimate support by the cloth on which it is spread. The cloth may to some extent be prevented from stretching by the manner in which it is held in the cell during a test. In the case of a sheet of rubber such as dental dam, the only support the rubber receives is from the screen on which it rests in the cell and the fact that it is clamped at the edges. In Fig. 5 are shown the graphs of several experiments where the pressure of the hydrogen was varied. The two balloon fabrics (Nos. 50,313 and 47,174) show about the same small rate of increase of permeability with increase of pressure. The two samples of dental dam show a slightly higher rate. The extensibility of rub-

FIG. 4. RELATION BETWEEN PERMEABILITY AND PARTIAL PRESSURE OF CARBON DIOXIDE

ber and cloth may vary so greatly that no great uniformity in the shape of these curves can be expected and, in general, that is our experience.

RELATION OF THICKNESS OF RUBBER TO PERMEABILITY

The permeability of a sample of rubber should obviously bear some relation to the thickness of the material. The most reasonable assumption, and the one usually

made, is that the permeability is inversely proportional to the thickness of the rubber. A series of samples of rubber, identical in chemical composition and physical properties, was not available for testing this point. It was necessary, therefore, to use material from different sources and varying in composition. The samples tested varied from the thin sheet rubber known as dental dam, about 0.2 mm. in thickness, up to sheets of 2 mm. thickness. Certain of the samples were "vapor cured" with sulphur chloride and the rest steam cured in the usual manner. The permeability of these samples was determined with zero difference of pressure on the two sides of the samples in order not to introduce any variation in the tests because of stretching of the material. Their permeability was determined with a Shakespere permeameter which was furnished to us by Prof. Shakespere of Birmingham University. For descriptions of this apparatus and method the reader is referred to Reports of the British Advisory Committee for Aeronautics for the last two years, which will undoubtedly be made available eventually. The instrument gives reproducible results of good precision for purposes of comparison.

The results of these tests are shown in Fig. 6, where the gas impedance, by which term the reciprocal of the permeability is designated, is plotted as a function of the thickness. There is clearly a linear relation between the two variables over a considerable range. Such uniformity as was found was hardly expected, considering the fact that the samples represented the product of a number of different makers and made no pretense of being uniform in composition. It will be noted that the very thin samples, about 0.2 to 0.3 mm. in thickness, show a lower impedance (higher perme-

FIG. 5. RELATION BETWEEN PERMEABILITY AND TOTAL PRESSURE OF HYDROGEN

ability) than corresponds to the straight line. This may possibly be due to the greater effect of non-uniformity in the very thin material. The sample, 0.9 mm. in thickness, which showed an impedance of over 0.6, was old and stiff and its high impedance was anticipated because of our observations on the decrease of permeability with age. This might also be inferred from its high acetone extract and combined sulphur values. The sample 1.93 mm. in thickness contains glue, which may account for its slightly greater impedance.

The results of Fig. 6 show sufficient uniformity to

warrant calculating what may be called the specific permeability of rubber. It may be defined in terms analogous to those in which such a property as thermal conductivity is defined, by stating that it is the volume of gas which passes through unit area of a sample of unit thickness in unit time with a difference in partial pressure of 760 mm. of the gas. The centimeter and minute can be conveniently used as units. The specific permeability to hydrogen at 25 deg. C. of vulcanized rubber of the character tested as calculated from the graph of Fig. 6 is 20.4×10^{-6} c.c. per minute. The

FIG. 6. RELATION BETWEEN PERMEABILITY AND THICKNESS OF RUBBER

volume of hydrogen (measured at 0 deg., 760 mm.) passing through a sample of rubber at 25 deg. C. can be approximately calculated from the following equation:

$$V = \frac{20 \times 10^{-6} \times A \times t}{d}$$

where V is the volume in c.c., A the area in sq.cm., t the time in minutes, and d the thickness in cm.

The only other data in the literature which can be compared with the above value are those of Kayser.⁵ The specific permeability to hydrogen at 25 deg. C. as calculated from Kayser's equation is 27.4×10^{-6} c.c. per minute, which value is in fair agreement with ours. Although care should be taken not to place too great reliance on any value for the specific permeability of rubber the characteristics of which are unknown, nevertheless the preceding equation will be found useful in arriving at an approximate figure in many cases. A direct permeability determination is the only sure method in any case.

The data of Fig. 6 confirm the very interesting observation of Prof. Shakespere that the gas impedance for a given weight of rubber is greatly increased by being spread on cloth. For example, a sheet of rubber (density 0.96) having a weight of 120 g. per sq.m. (about 3.5 oz. per sq.yd.) will have a thickness of 0.13

mm. and, according to Fig. 6, a permeability of $\frac{1}{0.042} =$

23.8 liters. This weight of rubber properly spread on cloth can be made to give a fabric having a permeability of about half that value, or 10 to 12 liters. The cloth therefore performs a very important function in reducing the permeability in addition to giving the rubber support and protection. As pointed out by Prof. Shakespere, this fact is of importance in securing balloon fabrics of the lowest permeability.

TIME OF PENETRATION OF RUBBER

For some purposes, notably for use in gas masks, it is not the maximum permeability which is of most

⁵Kayser, *Wied. Ann.*, vol. 43, p. 544; 1891.

importance, but the time required for the gas to penetrate the fabric. A gas mask fabric loses its protective value about as soon as the poison gas penetrates in appreciable quantities. Permeability determinations of the kind considered in the present work are therefore of very little value in this connection.

One test made on a balloon fabric with the Shakespere permeameter indicated that hydrogen penetrated the fabric in less than 1 minute and the fabric reached its maximum permeability in from 1 to 2 minutes. These times include the lag of the instrument so that the actual time required to penetrate this fabric must be very small. The permeability of this fabric was about 8 liters per sq.m. per 24 hours. Tests made with hydrogen sulphide, in which the gas penetrating the rubber was detected with lead acetate solution, showed that rubber films of the character used in balloon fabrics were penetrated with great rapidity by hydrogen sulphide also. Any considerable time required to reach equilibrium in testing may be generally considered to be caused by instrumental lag. Sometimes, however, there are actual changes in permeability with long continued tests, which make it appear that equilibrium is being reached very slowly.

RELATION OF PERMEABILITY TO TEMPERATURE

Graham first called attention to the large temperature coefficient of permeability. The relation between temperature and permeability has been examined since then by a number of investigators, most of whom are

FIG. 7. RELATIVE PERMEABILITY OF RUBBER TO CARBON DIOXIDE, HYDROGEN AND HELIUM AT VARIOUS TEMPERATURES

in general agreement, although Frenzel's* results alone indicate that the relation is a linear one. However, there are no reliable values which cover a very large range of temperatures.

A special cell was designed for determining the permeability at different temperatures. It was similar to the regular cell, except that each half was provided with a water jacket through which water could be circulated

by means of a pump. By regulating the temperature of the water, the fabric could easily be kept at any desired temperature within the range covered. The temperature of the fabric itself was measured by means of a copper-constantan thermocouple of No. 36 wire whose "hot junction" was mounted on the fabric before assembling the cell.

For graphic comparison the relative permeabilities of carbon dioxide, hydrogen and helium are shown in Fig. 7. It will be noted that the curves for hydrogen and helium show about the same relative increase with temperature. The change of permeability to carbon dioxide, however, becomes practically linear after 30 deg. C. No simple relation between permeability and temperature has been discovered.

(Part II of this paper will be published in our next issue.)

Grave Shortage of Print Paper in United Kingdom

If the difficulties of the American newspaper publishers are considerable, they are perhaps not more embarrassing than those of their British confrères. In November last the price per ton in Scandinavia of mechanical pulp was 120 crowns, as against 330 crowns today. (The normal exchange value of the crown is \$0.268.) The Scandinavian association virtually controls the market, and Lord Northcliffe's press remarks that there is nothing to prevent it from raising the price to 600 or even 900 crowns.

The *Times*, in reviewing the situation, concludes that the paper trade cannot become easier until the supply of mechanical pulp wood is enormously increased, and suggests that this be done by opening up the vast region lying between Hamilton Inlet and Lake St. John in Canada, where there is a supply of the right sort of timber sufficient to furnish the requirements of the country for years to come and where mills laid down today could be worked in eighteen months. It is explained in detail that wood can not be imported into Great Britain to be pulped on account of the expense and other insuperable difficulties.

The *Newspaper World* states that 321 newspapers have increased their price during the present year. The journal continues:

An analysis of the Board of Trade returns for the past four months shows that the average price for mechanical pulp has risen in the course of six years from about £4 10s. (\$22) per ton to about £24 (\$117) per ton, and for high-grade pure sulphites from £10 (\$48) a ton to between £50 and £60 (between \$243 and \$292) per ton. Seeing that the cost of all other raw materials and chemicals is double or treble what it was, and workers' wages are, reckoned according to the time worked, more than double, it is little wonder that pure white printings at 2d. (\$0.04) per pound are things of the past, and likely to be, so long as this generation lasts.

The action of the Norwegian Government with regard to paper may have an effect upon the quantity of pulp coming across to England. Some think that it will reduce the tonnage of paper being made in that country, so that the pulp mills will have more for export and will be willing to sell at a reduced price; but others consider that, as the pulp mills and paper mills so often belong to the same companies, they will want to make up on the pulp for anything they may lose on the paper from home consumption, and so will keep up the price as at present or even force it higher. If mechanical pulp advances much more, the British paper makers will be compelled to turn their attention to waste paper as a raw material to a far greater extent than they do now.

*Frenzel, Über die Gasdurchlässigkeit der Ballonstoffe." Druckerei des Elsassischen Textilblattes im Gewerbe.

British Nitrogen Production Plans

BY FREDERICK E. HAMER

THE experimental factory which the British government set about establishing during the war at Billingham-on-Tees, in the County of Durham, for the fixation of atmospheric nitrogen is at last to be turned to commercial and national account. The history of the enterprise is still somewhat obscure, and if it were fully disclosed would probably reveal the usual confusion and delays which characterize State action in such matters. It is not strictly correct to speak of a "factory." Such an establishment was contemplated and plans had been nearly completed, but with the signing of the armistice operations came to a stop. Billingham at present is understood to be little more than a site, with some partially constructed roads, a few foundations for plant, hutment accommodations for workers, etc. But as regards plant, there is practically none, and the Billingham "factory" is, like the nitrogen to be fixed, something in the air.

Of late there has been much speculation as to what was to become of the government's scheme, together with the results of the valuable research work undertaken. It is a relief to know that at last the matter has been finally settled on what is generally regarded here as a satisfactory basis. The great firm of Brunner, Mond & Co. has formed a new company, Synthetic Ammonia & Nitrates, Ltd., with a capital of £5,000,000, to take over the whole concern from the government. The company is to be British-controlled, the directors are to be British-born, and the first directors are to be approved by the government. The purchase price has not been disclosed.

LARGE TECHNICAL STAFF ORGANIZED

In addition to acquiring the site and what stands on it at Billingham, the new company will take over the leading engineers and chemists employed by the government in research work on the subject, and with these as a nucleus has already organized a large staff of scientists and technologists. Members of this staff have already visited and inspected the German plant at Oppau, where the Haber process had been worked out. The company's experts have also visited the U. S. Government plant at Sheffield, Ala., and the General Chemical Co.'s plant at Laurel Hill, N. Y. The experimental plant of M. Georges Claude at La Grand Paroisse has likewise been inspected, and in addition the experimental plant of Dr. Maxted, one of the leading British authorities on nitrogen-fixation, has been acquired. With this very complete equipment, and with the independent research and design carried out by the company's own staff, it is claimed that the British company is now in a position to erect plant "in the full confidence that the process chosen will prove to be superior to any now in existence."

MODIFICATION OF THE HABER PROCESS CHOSEN,

The process is essentially a modification of the Haber process and was developed without any German assistance. In the matter of patents, however, the company will be fully protected by the government against German interference. It is intended to erect immediately at Billingham a plant for the manufacture of 100 tons of 100 per cent ammonia per day, equal to 150,000 (rising to 450,000) tons of sulphate per year.

It is held, however, that chloride of ammonia is equal, if not superior, to sulphate as a fertilizer, and since by converting the ammonia into this form, carbonate of soda (soda ash) can be produced (a product in which Brunner, Mond & Co. are pre-eminent), it is hoped that the agricultural community will adopt the chloride for agricultural purposes.

So far the scheme is purely commercial, but national safety in the event of another war is amply provided for—it has been, in fact, all through the primary consideration. Arrangements have been made with Explosives Trades, Ltd., to take its requirements of ammonia from the company, and to erect plant to the extent desired by the government for the oxidation of this ammonia to form nitric acid and explosives derived therefrom. The scheme generally is regarded as well planned to safeguard British interests as regards fertilizers and (in the event of war) explosives.

ANOTHER COMPANY TO USE CLAUDE PROCESS

Side by side with this plan may be mentioned the purchase by an English company, Cumberland Coal, Power & Chemicals, Ltd., of the rights in the Georges Claude process, which works up to pressures of 1,000 atmospheres, and which, it is claimed, is peculiarly economical on account of its simplification of plant. So far no operations have been started in England, but a director of the company informs the writer that the operation of the first commercial unit in France is most satisfactory and when the tests have been fully completed an immediate start will be made here. The first unit to be installed will correspond with a production of 50,000 tons of sulphate of ammonia a year, and in addition a small plant will be erected for the production of chloride of ammonia, this company, like the other, having a strong belief in the future of chloride as a fertilizer.

These plans contemplate an enormously increased use of ammonia in some form for agricultural purposes, and they fit in with the national demand for bringing more land into cultivation and for introducing intensive methods of cultivation to safeguard the nation against the threatened shortage of foodstuffs.

London, England.

Electrical Sterilization of Milk

The British Medical Research Committee has recently, according to *Commerce Reports*, published results of experiments in sterilization of milk by Profs. Beattie and Lewis of Liverpool University, who largely carried on the work. They enumerate the results of fifteen experiments under varying conditions, with different degrees of current and with several qualities of milk. The final conclusions arrived at by the investigators are:

Milk can be rendered free from *B. coli* and *B. tuberculosis* by the new electrical method without raising the temperature higher than 63 or 64 deg. C. This temperature effect is very short in duration and in itself is not the principal factor in the destruction of the bacteria. Though the milk is not sterilized in the strict sense of the word, the percentage reduction of the bacteria over a fortnight period is 99.98. The keeping power of the milk is considerably increased.

The taste of the milk is not altered, and so far as careful chemical examination can determine the properties of the milk are not in any way impaired. The milk may accurately be described as "raw milk" free from pathogenetic bacteria.

Oxygen the Prime Factor in Corrosion*

A Discussion of the Nature of Passivity, and the Various Characteristics of Rust and Other Oxygen-Bearing Substances in Promoting Corrosion—It Appears Impossible to Produce a Micro-Section Which Will Corrode Under Water Attack According to Crystalline Areas

By WILLIAM D. RICHARDSON

ONE who has followed the experimental work done on the corrosion of iron and steel during the past ten or fifteen years must have noticed the apparently contradictory nature of many of the experimental results and conclusions drawn from them and must have felt that the theory of corrosion lacked some essential factor or factors to make it even an approximately complete generalization. No chemist today can safely predict on the basis of theory what metal or metals will corrode most or least under a given set of conditions, even with the results of the very large number of experiments made by different investigators before him. In any given set of circumstances wherein iron and steel are exposed to the weather or to conditions which favor corrosion, there is always a doubt as to which of several metals will have the longest life and how the corrosion or pitting will proceed. The common statement of the theory of corrosion based on Nernst's theory of electromotive force,¹ while entirely convincing in the abstract, fails, when subjected to test, to explain the experimental results obtained. However, the electrolytic theory undoubtedly includes all the fundamental facts, and if it fails to explain the course of corrosion in any given instance, this is probably because some essential facts have been overlooked or have not been sufficiently emphasized and correlated.

POTENTIAL DIFFERENCE—SOLUTION PRESSURE

Corrosion depends in part on the solution pressure of iron and its place in the electrochemical series. While varying somewhat with the nature of the electrolyte used, this series as commonly given is as follows, beginning with oxygen at the negative end and ending with caesium at the positive end of the series. Hydrogen is placed differently in different tables, in some being shown as more, in others less electropositive than iron. The very lack of agreement on the exact position of a given element in the electrochemical series indicates the influence of lesser factors in locating the element in one position or another. These factors are in general

ELECTROCHEMICAL SERIES OF THE ELEMENTS

		Aluminum	

similar to those which influence and modify the course of corrosion.

*Extracted from a paper on "Experiment on the Corrosion of Iron and Steel" presented before the American Institute of Chemical Engineers, June meeting, 1920.

¹Whitney, *J. Am. Chem. Soc.*, vol. 25, p. 1894.

In order to ascertain the place of hydrogen in relationship to iron in the electrochemical series, the following experiment was tried based on the well-known fact that a pure or nearly pure iron when soaked in dilute sulphuric acid absorbs considerable quantities of hydrogen.

Two strips of pure open-hearth iron, measuring about 1 x 3 in., were carefully cleaned by means of fine emery paper. One was allowed to soak in sulphuric acid of something less than 1 per cent strength over night. In the morning the untouched piece of metal, still bright, was once more polished with fine emery and both pieces were connected through a sensitive millivoltmeter and simultaneously plunged into neutral salt solution. The voltmeter showed the acid-soaked iron positive and the clean iron negative.

On the face of it this experiment indicates that hydrogen, or rather iron with hydrogen occluded, is electro-positive to clean iron, but it was considered that the experiment might only prove that completely reduced iron (iron with hydrogen occluded) was electro-positive to iron with oxygen condensed on its surface (clean, bright iron). However, the conditions of the experiment were similar to those which might obtain during corrosion, so that it may be accepted for practical purposes that iron with hydrogen occluded on its surface or any area of iron with hydrogen occluded is electro-positive to clean, bright iron and, of course, more so to iron with occluded oxygen or coated with oxides of iron. This holds true for water, neutral salts and generally for dilute non-oxidizing acids.

FACTORS INFLUENCING CORROSION

The main factors influencing corrosion considered in this paper are four in number:

1. Composition of the metal.
2. Physical treatment to which the metal has been subjected.
3. The influence of atmospheric oxygen (and other atmospheric constituents).
4. The influence of the products of corrosion or rust.

COMPOSITION

According to the electrolytic theory, based on the solution pressure hypothesis of Nernst, corrosion of iron has been held by many chemists to be determined by the composition of the metal, and perhaps the majority of papers written on the subject take this point of view. All of the kinds of iron and steel investigated by the writer corrode easily with the single exception of Duriron². There must be some point, more or less

²This metal is stated to contain approximately 15 per cent silicon and hence is an alloy of so different a composition from the other metals considered as to require entirely separate treatment. It is possible that there are no or few ferrite areas or surfaces exposed in this alloy and hence little opportunity for iron, owing to its solution pressure, to go into solution under any conditions even in the presence of strong and weak acids.

critical, at which corrosion or corrodibility rapidly diminishes or ceases, and the study of the composition corresponding to this point or curve region should throw much light on the general problem of corrosion. For present purposes only the ordinary types of iron and steel are under consideration and any statements made, if not otherwise qualified, refer to such varieties. Further discussion of the influence of composition on corrosion will appear later.

PHYSICAL TREATMENT

Under physical treatment are to be considered the various heat treatments, working the metal under heat, rolling and annealing, method of manufacture, etc. Some of these treatments change the composition of the metal, others only its physical structure, or, more important, its surface, and corrosion, it may not be amiss to emphasize, is distinctly a surface phenomenon. There are occasions then when physical treatment may be more important in influencing the commencement and course of corrosion than composition itself. Where deep pitting or slight but uniform general corrosion takes place its progress may be determined by so simple a factor as mill scale remaining closely adherent on certain parts of an iron surface only, and again corrosion may be prevented entirely for a long period of time by thin tightly adherent mill scale.

OXYGEN

Oxygen is considered by the writer to dominate over composition in determining the initial stages of corrosion and, acting through the medium of the products of corrosion, in determining more than any other single factor its entire course. Water is, of course, always assumed to be present either continuously or intermittently. It is possible that some corrosion results which have been reported as due to composition of the metal may have been due and perhaps determined by the physical treatment to which the metal has been subjected. On the other hand, atmospheric air or oxygen, and particularly the products of corrosion, are able to overbalance physical treatment as they are composition.

PRODUCTS OF CORROSION

The products of corrosion are themselves great accelerators of corrosion, just as mill scale is. This accelerating action is due first to the fact that the iron oxide formed during corrosion is strongly electro-negative compared to iron and when concerned in corrosion is always a cathode. Ferric oxide may also act as a depolarizer in corrosion, since it is oftentimes reduced to Fe_2O_3 . Its activity may be increased by condensation or adsorption of atmospheric oxygen on its surface, although Friend believes his experiments have disproved this. It also acts by absorbing and holding water.

After the commencement of corrosion, its subsequent course is determined very largely by the physical character of the rust formed, its distribution over and its adhesion to the surface of the metal. It may so act as to stimulate general corrosion. It may be responsible for deep pitting or under other circumstances may retard corrosion or prevent it altogether, for considerable periods at least, by close adhesion over considerable areas. It may cause corrosion to take different courses at different times, due to the fact that the rust formed at one time may be loose and wet, later on tightly adherent and later still dry and hard, so that by the

influence of moisture or temperature or physical strain it scales off from large surfaces, exposing the metal beneath, and the cycle is thus renewed. Altogether rust appears to be the main feature of ordinary corrosion, not only as a result, but as a causative agent.

Rust itself is dependent for its formation upon atmospheric oxygen with the slight assistance of carbon dioxide and its physical characters are developed chiefly by the conditions of corrosion. The behavior of the rust formed may also be dependent upon the physical treatment to which the metal has been subjected and to the composition of the metal, so that the conclusion appears warranted that composition of the metal, at least among the ordinary varieties of iron considered here, does not influence the progress of corrosion directly but rather indirectly through the behavior of rust and the relationship of the rust to the metal composition and surface.

Thus the products of corrosion or rust act in a dual capacity, electrochemically as accelerators of corrosion and physically as a protective against corrosion. It is needless to point out that these two ways of functioning are diametrically opposed to each other and it can easily be imagined how many types of corrosion and peculiarities and apparently unexplainable differences in corrosion might be due to this fact alone.

RELATIVE IMPORTANCE OF COMPOSITION, OXYGEN AND IRON OXIDE

The relative importance of these three factors of corrosion, and particularly the importance of composition, is of paramount interest. If oxygen determines the commencement of corrosion, and iron oxide and other products of corrosion determine its subsequent course, of what possible influence can the composition of the metal be? Composition of the metal is the one factor which can be more or less controlled for a given service. It is unthinkable that composition should not have some influence of corrosion. It is well demonstrated that irons containing much silicon, for example, do not corrode under ordinary circumstances and are very nearly insoluble in the common acids. Iron containing much nickel is also practically non-corrodible. Ordinary cast iron under many conditions corrodes less than steel or mild steel. These are well-known facts and our theories of corrosion must take them into consideration.

Apparently composition of metal does not influence corrosion directly, if we consider the ordinary varieties of iron and steel. However, the composition of the metal evidently does influence the course of corrosion profoundly in an indirect way through the influence of the products of corrosion. We have seen that the products of corrosion may behave in three different ways in influencing the course of corrosion:

1. The rust formed may fall or scale off.
2. The rust may be partially adherent and an accelerator.
3. The rust may be protectively adherent.

Naturally there may be also some intermediate stages between these three principal divisions. The physical and electrical behavior of the rust are dependent upon two factors:

1. The conditions under which the corrosion takes place.
2. The composition of the metal.

Thus, of two different metals of different compositions but subjected to the same circumstances as regards corrosion, the rust in the one case may act as an accelerator of corrosion and in the other may tend to

act rather as protective coating. In other words, the rust may tend to adhere less in one case and more in another, over smaller areas in one case and over larger areas in another, and thus, under the same conditions, one metal will corrode more and another of different composition will corrode less.

The correlation between composition and the behavior of the products of corrosion on the basis of this theory of indirect influence of composition of the metal is most important but requires a vast amount of work to bring it to a satisfactory and practical conclusion. If hydrogen is included as one of the products of corrosion, the phenomenon of polarization as a negative influence in corrosion should also be included; but in this paper by "products of corrosion" are meant the hydroxides, oxides and carbonates of iron produced during rusting in water and the salts and basic salts in salt solutions.

CORROSION OF POLISHED IRON SURFACES

A perfectly polished iron surface consists of a film of pure iron spread over the entire metal surface and covering pure iron and impurities alike. The pure iron is apparently caused to flow in such a manner as to form a mirror-like film, under the influence of the polishing powder and the friction induced by the polishing mechanism, whether hand or machine. On such a polished surface corrosion starts with some difficulty, compared with ordinary smooth, clean iron, and more particularly with rather rough but clean surfaces. It is also less easily attacked by acid. As is often found to be the case in metallographic work, when etching the polished specimens the higher the polish the more difficult it is to start the etching. Nevertheless if a drop of very pure redistilled water be placed on a highly polished iron or steel surface and allowed to dry, a spot of rust will be left. As a rule, the higher the polish the smaller will be the amount of rust remaining, and since samples of pure iron or steel take a higher polish than cast irons, the rust spot on polished cast iron is usually more prominent than on polished pure irons or steel.

If metals are polished to a high degree with perfectly dry and grease-free abrasives, a drop of water, instead of spreading over the surface, rolls up into a spheroid as though in contact with an oily surface. If the metal is capable of taking a very high polish, rust formation begins slowly at a few points only, and after the drop has dried only a small residue of rust remains, sometimes in the form of a narrow rim around the place where the drop stood. Less pure irons such as cast iron and semi-steel, which, as a rule, do not take as high a polish as pure irons and steels, also cause a drop of water to assume the spheroidal shape, but corrosion begins at numerous points and much sooner than in the other cases. In such water-drop experiments the progress of corrosion can be followed by means of a microscope or hand lens, as the greenish-white ferrous hydroxide spreads outwardly through the water from the points at which the corrosion is occurring and gradually oxidizes to red rust.

After corrosion test on polished surfaces, whether either plain water or the ferroxy indicator in agar is used to cover an area of several inches square or more, it usually happens that there are more and larger electro-negative areas left with their original bright polish, on highly polished and comparatively pure samples than on less polished and comparatively impure samples.

The fact that the highly polished surface of iron

starts to corrode more slowly than the less polished surface, such as that of cast iron or relatively less pure metal, might seem to hold out a faint hope that extreme purity of metal, if possible of attainment in a practical way, would be a means of reaching the much desired goal of corrosion-resisting iron. However, this hope does not seem warranted by the facts. Very pure open-hearth iron corrodes in the presence of oxygen more rapidly than cast iron. Electrolytic iron corrodes readily. Even highly polished surfaces corrode slightly in the beginning and at an accelerated rate after the first rust spot is formed. So long as oxygen is the dominating influence which governs the commencement of corrosion, and rust and oxygen together control the subsequent course so largely, neither pure iron nor polished surfaces appear to offer the solution of the problem.

PASSIVITY OF IRON AN OXIDATION PHENOMENON

When either commercial or electrolytic iron is immersed in strong oxidizing agents, such as chloric, chromic or fuming nitric acids, or when touched with gold or platinum while dissolving in nitric acid of sp.gr. 1.35, or when heated momentarily in air, or when it is made the positive electrode in an electrolyte containing oxygen, it becomes passive and thereafter is not attacked by ordinary acids, no longer precipitates copper, silver or lead from their salts, and in general behaves like a noble metal.

All of these processes for producing passivity in iron are oxidizing processes.

Passive iron may be reactivated by heating in a reducing atmosphere, by the action of water, salt solutions, the diluted common acids, by making it the cathode in an electrolyte, and by other means.

All of the processes for reactivating passive iron are reducing processes, since hydrogen is disengaged in all of them, including contact with water and salt solutions, as in the ordinary processes of corrosion in water.

The oxide theory of passivity apparently offers the best explanation, and even though no actual oxides are formed on the surface of the iron, an equivalent gain in valence or loss of electrons can be visualized by the oxidation hypothesis and suggests an interesting parallelism between passive iron and iron covered with mill scale and adherent rust. This parallelism may be stated as follows:

If all exposed pure iron surfaces in the crystallographic sense are uniformly covered by a layer of oxide either thin or thick, and if this film be tightly adhering, no corrosion takes place. A sub-microscopic film may be assumed to be produced over an iron surface by immersion in strong oxidizing agents such as chromic and nitric acids (the passive layer), a thicker and visible layer by an oxidizing flame (mill scale) and a more irregular and thicker layer during corrosion under

¹Dr. H. G. Byers does not accept the oxide theory of passivity, although he offers no substitute. Abstracts of his extensive investigations are found in *Chem. Abs.*, vol. 3, p. 274; vol. 4, p. 1933; vol. 6, p. 452; vol. 7, p. 318; vol. 7, p. 3268; vol. 8, p. 3738; vol. 10, p. 717. The original papers are as follows:

certain conditions (rust). All three types of oxide layers protect against corrosion. However, if portions of such surfaces are removed by either physical or chemical means, corrosion starts at once, the abraded or dissolved areas becoming electro-positive and the oxide areas electro-negative. In all cases corrosion is prevented or delayed until the film of oxides is lifted or removed. Iron surfaced in any of these ways may in a very large and general sense be considered passive as regards corrosion in substantially the same sense, namely, by the uniform action of oxygen on exposed ferrite areas. There may be some doubt about the exact condition of the surface in passive iron induced by treatment with oxidizing agents, one view holding that the surface is simply polarized, another that it holds condensed or occluded oxygen and another that a sub-microscopic layer of oxide has been formed, but there can be no difference of opinion about oxygen being the active agent. In the case of iron surfaces coated with magnetic oxide, the nature of the protection against corrosion is obviously both electrical and mechanical. When such a protective layer of magnetic oxide is lifted from the iron surface in places by a film of water or is removed from certain areas mechanically, the remainder acts as an accelerator of corrosion and deep pitting generally results. This is also true for adherent rust. It probably would hold for passive areas provided these could be maintained in place for considerable periods of time.

FERROXYL INDICATOR ON POLISHED AND ETCHED SURFACES

If the entire surface of a clean piece of iron be moistened and if the surface be free from oil or grease so that the water spreads over it rather uniformly, certain irregular areas will be covered with rust and other areas will not—the rusting will not be uniform, although the rust areas in some cases are large patches and in other cases very small, in the form of specks or flakes of rust. If initial rusting were guided and determined by the composition of the iron, one might naturally expect that the rusted areas would bear a definite relationship, when examined under the microscope, to the crystallographic structure of the metal and that if the corrosion took place under carefully regulated conditions the ferrite areas would become anodes and produce rust spots corresponding to them in area and that various segregated impurities in the iron would become cathodes and would remain bare of rust in the initial rusting, or until colloidal ferric hydroxide, moving with the electrolytic currents of corrosion, deposited on them. Nothing of this sort can be observed under the microscope, however carefully the rusting process is conducted.

In order to ascertain whether in fact ferrite areas are by their nature anodes and areas of impurities cathodes, in the rusting process, use was made of the very sensitive indicator developed by Messrs. Cushman and Walker and named by them ferroxy indicator. Samples of all of the irons used were polished on the wheel in the ordinary way and slightly etched by nitric acid in alcohol. After the etching the acid was removed by immersion in successive beakers containing absolute alcohol and ether. Different procedures were followed, some of the samples being dried after alcohol treatment and some after ether treatment. Duplicates were dried in the air and in hydrogen and various modified manipulations were made use of. Standard ferroxy indicator

in agar was dropped on the surfaces thus prepared and observations were made by means of a microscope of moderate power. The crystallographic structure of the metal could be readily seen and the development of the blue and red areas in the jelly could also be followed. If initial corrosion were determined by the composition of the metal, the red and blue areas should bear a definite relationship to the crystallographic structure of the metal and it would be natural to expect blue areas to form only over ferrite areas and red over impurities of various sorts. However, the red and blue areas in no case bore any definite relationship to the crystallographic structure. By no manipulation which was used could red and blue areas be made to coincide with crystallographic areas.

I do not wish to convey the impression that it would be impossible to refine the manipulation to such a degree that this correspondence might not be brought about, but in any of the manipulations adopted with any of the samples experimented on it did not occur. Mild alkaline solutions were tried for the neutralization of acids used in etching, the alkali afterward being removed by absolute alcohol and ether and the drying being conducted both in air and hydrogen. But in this series of experiments the results were like the previous ones in that there was no correspondence between crystallographic areas and anode and cathode areas as indicated by the ferroxy reagent.

OXYGEN DOMINATES IN INITIAL CORROSION

All of the above experiments indicate what must have been thought by many experimenters on corrosion, that some influence dominates the composition of the metal in determining at what points or over what areas the initial corrosion may begin. This dominating influence in initial corrosion is undoubtedly oxygen. It may be oxygen which has been occluded or adsorbed by certain areas of the metal as opposed to other areas or it may be that some oxide or sub-oxide has been formed on certain areas in the form of an invisible film, but in any case the determining influence is oxygen, whether free or in combination or held to the surface by occlusion or adsorption. That it dominates over metal composition in the initial stages of corrosion can readily be demonstrated by the fact that the red areas produced by the ferroxy indicator extend over comparatively large surfaces, considered from the standpoint of crystallography, including very many ferrite crystal surfaces in the case of a mild steel or pure open-hearth iron.

It might be argued that the preliminary treatment of the polished samples, such as the etching with an oxidizing acid, removal of the acid and the drying in air, superimpose such conditions on the iron surface that certain comparatively large areas, at any rate larger than the crystallographic units, become electro-negative under conditions favoring corrosion. It should be noted, however, that while all the samples were etched by means of nitric acid, some of them were dried in oxygen and others in hydrogen. Etching, itself, by means of acid, is a form of corrosion, and on the basis of the accepted theory presupposes polarity on the polished surface. The etched surface would not be visible under the microscope were not certain crystallographic areas attacked by the acid and certain other areas left unaffected. Etching then follows the crystallographic structure of the metal, as would be expected, and if polarity is induced by the etching process, one would naturally expect that this polarity would also be

definitely related to the crystallographic structure. We might assume that a given sample of polished iron or steel at the conclusion of the etching process would be in such condition that the subsequent corrosion under ordinary atmospheric conditions would be initiated in strict conformity with the crystallographic structure and the first corroded areas patterned after that structure. Whenever the corrosion takes place under atmospheric conditions or under water saturated with air, this is not the case. Hence again the conclusion seems warranted that some influence dominating over composition and structure of metal determines the initial course of corrosion.

Why the oxygen of the air influences considerable areas to become electro-negative is difficult to say. An ordinary iron surface is a very sensitive one as regards corrosion. The slightest film of iron oxide over pure iron makes such an area electro-negative. Areas which appear tarnished and exhibit thin-film color phenomena are electro-negative with reference to non-tarnished areas. The tarnish probably consists of an extremely thin film of iron oxide or, if the area has been in contact with acid, of an iron salt, probably a ferric salt. Everything indicates that the ordinary clean iron surface is exquisitely sensitive to numerous influences affecting corrosion, chief among which under ordinary circumstances are oxygen and the oxides of iron or rust.

THE RÔLE OF OXYGEN

The importance of oxygen in the corrosion of iron was pointed out by William H. Walker as early as 1907 and was emphasized by him and others subsequently. Walker is of the opinion that when oxygen acts in such a way as to further the process of corrosion it does so by its action on the hydrogen film which otherwise would bring the action to a close. That this action occurs and that it is catalyzed under certain conditions more than others cannot be doubted, but there is also the explanation that it may act simply and directly on the ferrous ions, changing them to ferric, and thus permitting more ferrous ions to enter the solution to restore equilibrium. At any rate, this would seem to be an explanation which accounts for the marked difference in behavior under corroding influences in the absence and presence of oxygen of such bivalent metals as aluminum and zinc as compared with iron and manganese, which are both capable of forming higher oxides and hydroxides. Air and oxygen do not accelerate the corrosion of aluminum in the presence of water to any appreciable extent. It might be argued that this is due simply to the fact that the aluminum surface does not catalyze the oxygen-hydrogen reaction as does the iron surface. Against this we have the much greater solution tension of aluminum compared with iron, one volt for aluminum as compared with 0.06 for ferrous iron. This explanation also has the advantage of agreeing with what actually and visibly occurs in corrosion experiments.

THE RÔLE OF RUST

Perhaps the most definite statements concerning rust as an accelerator of corrosion come from Friend. Friend observes, "When iron has once begun to rust in air, further corrosion proceeds rapidly, until the whole surface of the metal is oxidized, even although the temperature of the air is well above dewpoint, so that a piece of bright iron exposed in a similar manner would

remain unaffected for an indefinite time." He rejects the suggestion of Kuhlmann* that rust acts as an oxygen carrier and thus catalytically assists further corrosion. He upholds the view held by Hutton, Grace Calvert, Wagner and Crum Brown to the effect that rust is decidedly hygroscopic and becomes, charged with water in an atmosphere in which bright iron would not be affected.

Friend's experiments, however, to prove that rust does not act as an oxygen carrier may not be entirely conclusive. None of the experiments precisely corresponds to rusting in air and in water.

Friend points out that the action of rust when iron is corroding in air and submerged in water may be different. In the latter case it acts as an accelerator on account of its electro-negative character.

* MILL SCALE VS. FERRIC OXIDE AS AN ACCELERATOR

Mill scale as a rule causes deeper pitting than rust, although ferric oxide, Fe_2O_3 , on account of its higher degree of oxidation, should be more electro-negative than Fe_2O_3 . The question naturally arises, therefore, Why does mill scale under ordinary circumstances act as a more powerful accelerator of corrosion? The answer is probably to be found in the different physical properties of the two substances as they usually occur. Ferric oxide is formed by dehydration of flocculent ferric hydroxide and is never as dense or as closely adherent as mill scale. The latter not only adheres closely but is very dense as usually formed by heat on the surface of iron and in addition is an excellent conductor. It is very difficult to obtain Fe_2O_3 of the same relative density and adhering to the surface in the same way as mill scale and it would be quite impossible to attain equal conductivity in the two substances.

DOES "BUSY IRON" CORRODE?

Engineers are unanimous in the belief that iron or steel in active service does not tend to corrode to the extent that idle iron or steel does; that the steel rail which carries many trains daily will outlast the rail carrying no trains; that the used hammer or other tool rusts less than the unused. The universal testimony of all observers indicates that their belief is well founded.

It may well be questioned whether there is anything intrinsic in use itself as affecting the metal physically, chemically or electrically, which would modify its corrodibility. The observed results are most likely due to surface changes induced by effects of service and may be explained usually by one or more of the following consequences of continued use:

1. The polishing effect of hammering or rubbing which, like all polishing actions, produces a surface which resists corrosion.
2. The shaking or rubbing off of all but tightly adherent rust which in the end forms a protective layer.
3. The accidental coating of the surface of the used iron or steel with oil or oily substances during use, which also prevents corrosion.

Cushman has suggested that continued vibration of iron or steel has the effect of equalizing potential differences, and Friend believes that in the case of "busy rails" the passage of trains keeps them above the temperature of their surroundings and tends to prevent the condensation of moisture on their surfaces. Sang has suggested that "vibration causes a shedding of the rust as soon as it is formed on the spots that are not

*Corrosion of Iron and Steel, pp. 96-98, 252-253.

*Dammer, Handbuch der anorganischen Chemie, 1893, III, 303.

protected by mill scale, and there is, therefore, no acceleration of the action due to the accumulation of spongy and electro-negative rust." Sang's explanation of one of the effects of vibration is undoubtedly correct as far as it goes, and Friend's idea also is undoubtedly true, but none of these explanations goes to the bottom of the matter.

The used rail or old tool generally presents two surfaces: one, a polished surface, as the head of a hammer or the top of a rail, the other a dull surface covered with brownish, black closely adherent rust, as the sides of a hammer or rail. The polished surface is naturally resistant to corrosion and the tightly adherent rust protects the iron under it. That neither type of surface rusts easily is a matter of common observation. Where these two types of surface join, there is, however, the likelihood of corrosion starting whenever suitable conditions arise, as when the iron or steel becomes idle.

When a railway rail remains idle for several hours during a rain the bright upper surface invariably becomes covered with rust, but if trains are passing at frequent intervals the rust either is not formed at all or is quickly removed.

No more than a mere mention of oil on used iron is necessary. Casual reflection will indicate to anyone that the used tool or machine (or even the steel rail), when there is no intention of oiling it, is more likely to have oil dropped upon it accidentally than the unused.

Perhaps a more correct statement than the usual one of the case of "busy iron" would be to say that (in the absence of oil protection) busy iron is protected on certain surfaces by polishing action, but that on surfaces where it does corrode, it corrodes in a self-protective manner.

Analysis of High-Speed Steel

BY H. O. WARD

THE following is an analytical method that fills a long-felt want in laboratories analyzing high-speed steel in quantity. The experimental work on the method was done in the laboratory of the National Twist Drill & Tool Co., Detroit, Mich., by the author, working in collaboration with J. G. Lahr, chief research chemist of the Studebaker Corporation of America. The original feature is the method for the solution of tungsten. The method is one for the determination of manganese, chromium and vanadium in high-speed steel, using a single sample and without filtering during the operation.

A 0.5-g. sample in a 600-c.c. beaker is dissolved with 50 c.c. of sulphuric acid-silver nitrate solution¹ by the application of heat. When solution is complete 5 c.c. of nitric-phosphoric solution² is added. (If the tungsten does not immediately disappear, boil until the solution assumes a clear green color.) The contents of the beaker are then diluted to 200 c.c. and about 1 g. of crystals of ammonium persulphate added in small successive portions. (This will oxidize, in order, the chromium, vanadium and manganese, the last appearing as permanganic acid, giving the solution a deep pink color.) The beaker is removed from the hot plate and cooled before titrating the manganese with standard sodium arsenite solution.³

The contents of the beaker are now diluted to 500 c.c. and heated to boiling. A few drops of hydrochloric acid are added to destroy the permanganate coloration and precipitate the silver nitrate. Continue the boiling for at least ten minutes to expel the excess of ammonium persulphate. Cool to room temperature.

The chromium is titrated by adding an excess of standard ferrous ammonium sulphate solution⁴, running in standard potassium permanganate⁵ to a pink color and, after stirring for thirty seconds, destroying the excess of permanganate with standard sodium arsenite solution.

The vanadium is determined immediately after the chromium by first adding 10 c.c. of standard ferrous ammonium sulphate solution, destroying the excess by adding 10 c.c. of ammonium persulphate solution⁶, and titrating with standard potassium permanganate (for vanadium) solution.⁷ Here again an excess of permanganate is added and titrated back with standard sodium arsenite solution (so using the same arsenite solution for the manganese, chromium and vanadium titrations).

CALCULATIONS

Manganese. Number c.c. of sodium arsenite solution divided by 5 multiplied by 0.1 = per cent Mn.

Chromium. Number c.c. of ferrous ammonium sulphate solution less number c.c. of potassium permanganate solution multiplied by 0.1 = per cent Cr. Ferrous ammonium sulphate must be corrected to the permanganate value before the subtraction and the permanganate corrected for the amount destroyed by the arsenite solution. The arsenite is compared to the permanganate to find out how many c.c. of arsenite 1 c.c. of permanganate is equal to. Then the number c.c. of arsenite used in the titration is divided by this value and the result subtracted from the permanganate used.

Vanadium. Number c.c. of potassium permanganate solution used less the arsenite as in the case of chromium determination multiplied by 0.2 = per cent V.

When the nitric-phosphoric solution is added it not only oxidizes the iron, carbides and tungsten present but also dissolves the tungstic acid formed, the tungsten forming a phospho-tungstate much the same as molybdenum will do under similar conditions. This saves the process of filtering. However, a little tungstic acid remaining in the solution will do no harm. If the solution is dark colored and not a clear green when diluted the first time, you may be sure it was not boiling when the nitric-phosphoric solution was added. The slight opalescence due to the presence of silver chloride in the solution will not be a detriment but rather a help, as it more distinctly shows the delicate color changes found in the chromium and vanadium titrations.

The arsenite determinations are recommended by several authorities such as Lord and Scott. The addition of the arsenite titration here adds probably 50 per cent more speed to the titration proper.

National Twist Drill & Tool Co.,
Detroit, Mich.

¹Ferrous ammonium sulphate solution. 11.1296 g. per liter c.p. crystals. 10 c.c. sulphuric acid (conc.). Standardize against permanganate.

²Potassium permanganate solution. 0.9117 g. c.p. crystals per liter. 0.02885 normal. 0.0580 g. sodium oxalate = 30 c.c. of solution.

³Potassium permanganate solution (for vanadium). 0.6200 g. c.p. crystals per liter. 0.01961 normal. 0.0403 g. sodium oxalate = 30 c.c. of solution.

⁴Ammonium persulphate solution. 125 g. per liter c.p. crystals.

⁵Sulphuric acid-silver nitrate solution. 3 l. sulphuric acid (conc.). 15 l. water distilled. 27 g. silver nitrate c.p. crystals.

⁶Nitric-phosphoric solution. 50 per cent nitric acid (conc.). 50 per cent phosphoric acid. U. S. P. syrup.

⁷Sodium arsenite solution. Stock solution: 4 g. arsenious oxide per liter. 16 κ. sodium carbonate per liter. Solution for use: 100 c.c. stock solution. 900 c.c. water distilled.

Electric Smelting of Iron Ore With Coke*

BY GEORG STIG, MET. E.

ALTHOUGH pig iron must be considered as a raw material, its manufacture is nevertheless one of the most important processes in the iron and steel industry. In order to satisfy the enormous and steadily increasing demand and to attain the best economical results, it has been found necessary to produce it with coke in furnaces producing quantities as large as 700 tons per day. The change from charcoal to coke as a reducing agent required more than 100 years and took place under great difficulties and with great expenditures. It was found that a charcoal furnace was not suitable for coke, and consequently the design of the blast furnace as well as the mode of operation had to be changed considerably before a suitable coke blast furnace was obtained. What chiefly contributed to the solution of the problem, except the change of shape, size, etc., was the increase in the temperature and the pressure of the blast.

When comparing the ordinary method for producing pig iron with the electrothermic process certain analogies will naturally be found and it might be said that the temperature and pressure of the blast in the ordinary process corresponds to the current density and the load in electric furnaces. Consequently when smelting with coke, the best results, technically as well as economically, will be obtained with furnaces capable of utilizing a great amount of power.

POSSIBILITIES OF DEVELOPMENT

It may be advantageous to enumerate here the present types of furnaces, their possibilities of development and as a consequence of this, their suitability for operation with coke. According to the principal characteristics of the designs they may be tabulated as follows:

1. With single shafts.
 - Electrometal.
 - Harmet, etc.
2. With several shafts.
 - Keller.
 - The California furnaces.
 - Heroult-Haanel-Tinfos.
 - Helfenstein-Kopparberg.

No results from operations on a large scale are obtainable from the Harmet and Keller types of furnaces, as they have been tried with loads of only 500-600 kw. The possibility of developing the Keller type is relatively limited and the same holds probably true also of the Harmet furnace, the roof of which will cause difficulties due to lack of cooling by gas circulation.

The California furnaces and the Helfenstein furnace (and its modification the Kopparberg furnace) are similar inasmuch as they are all polyphase furnaces with at least two shafts and have approximately the same possibilities of development. The size is limited only by the amount of energy the electrodes can carry and by the number of shafts, which, however, in very large

furnaces will be so many as to make the operation uneconomical; the upper limit of capacity is probably 5,000 to 6,000 kw.

The Heroult-Haanel-Tinfos type is somewhat similar to the Helfenstein-Kopparberg furnace. The principal difference consists in its being a single-phase furnace with a bottom electrode. However, the voltage between the transformer busbars is only half of what it is on other types. Consequently, in order to obtain a great load, very high currents must be employed. To carry a higher current than 50,000 amp., however, is probably uneconomical, so that the maximum load is not more than 3,000 kw. It must also be borne in mind that the leads on furnaces with bottom electrodes can not be arranged so satisfactorily as on furnaces without bottom electrodes, with the result that a considerable loss of energy in the leads must be counted with when running with a high load.

The Electrometal type has without doubt the greatest possibility of development. The largest furnace built up to date for electric production of pig iron is of this type, i.e., the furnace at Domnarfvet for 7,200 kw. From the designer's point of view it is, however, possible to build furnaces for 12,000 to 15,000 kw. provided electrodes of high quality are available.

FACTORS FOR SUCCESSFUL OPERATION WITH COKE

I am giving below the results I have obtained from operating the above-mentioned furnaces with coke, but will in this connection first point out that all the difficulties with coke operation which were experienced at the trial runs with the Electrometal furnace in Trollhättan and Hardanger, viz., bridging of the charge, cold iron, burnt roofs, etc., even the abnormally high current (with its corresponding low voltage) have occurred and occur occasionally not only in coke furnaces but also in charcoal furnaces and with all other types of furnaces. I know an electric furnace built for and operated with charcoal which exhibited the same irregular and impossible runs, as for instance the Hardanger furnace before it was rebuilt. This happened as late as 1915. It is surprising that anybody can imagine that the process will be improved only by pointing out these difficulties and consider them insurmountable; the cause ought to be ascertained in the first place and then the possibility of avoiding them discussed.

It has been shown from actual operations that the following factors are of great importance in order to obtain good results and to avoid the difficulties mentioned above:

1. The rate of melting.
2. The dimensions of the furnace hearth.
3. The shape and height of the furnace.
4. Voltage, current, current density and arrangement of the leads.
5. The composition of the charge.
6. The gas circulation (at the Electrometal furnace).

INFLUENCE OF MELTING RATE

In order to obtain a quiet and even run the melting rate is without doubt the most important factor, especially as far as the lower limit is concerned. The upper limit is not of the same great importance with furnaces without gas circulation. With furnaces of the Electrometal type, however, the highest efficiency is obtained when the gases leave the furnace at somewhat over 100 deg. C., in other words when the volume of the shaft is designed so that the melting rate is not too great.

*Translation from *Teknisk Ukeblad*, vol. 66, pp. 151-3, Jan. 24, 1919.

The writer has had practical experience with electric smelting of iron with coke as well as charcoal with furnaces mentioned below at Domnarfvet from 1911, or in other words from the time when this process was beginning to be used on a large scale. The following furnaces were in operation during this time:

Electrometal—Five furnaces, three of 2,800 kw., 7,200 kw. and 5,000 kw. respectively; one Helfenstein modification, of 4,000 kw.; one Kopparberg modification, of 5,000 kw.

Heroult-Haanel-Tinfos—Three furnaces, of 500 kw., 1,000 kw. and 1,000 kw. respectively.

When the melting rate is too low, short circuits and bridging of the charge often occur, and in this connection cold iron occasionally. My explanation for the occurrence of these irregularities is based on observations of a run with coke in Electrometal furnace with too large a shaft. The charge consisted exclusively of specular hematite which due to the relatively low melting rate was exposed to the reducing action of the CO gases for a very long time. During this preliminary reduction the hematite was disintegrated, and the charge descended to the crucible in the form of fine ore and coarse coke. The fines descended faster with the result that the coke accumulated in a charge between the electrodes. Now, when making artificial graphite from coke, for instance in electric furnaces, a little iron oxide is often added which acts as a catalyzer, facilitating the graphite reaction. It is therefore only natural to suppose that in the above mentioned case graphite was formed and as no more oxidizing material was added to the mass of graphite, it began to form a short circuit between the electrodes. The greater part of the fine ore descended directly to the iron and slag bath and caused a boil. It is therefore evident that bridging of the charge and cold iron may be caused simultaneously by too slow melting.

COKE TENDS TO GRAPHITIZE

It has been proven by electric measurements on the Domnarfvet and Söderfors electric furnaces made by the Electric Testing Bureau in Stockholm, that the electric current passes from one electrode to the nearest one and not, as had been previously assumed, to the one connected in series in a polyphase circuit; and, furthermore, that the drop in potential takes place principally in the electric arc and not in the charge. In consequence of this, the conductivity of the charge is of minor importance, a fact which has been confirmed in practice when melting, for instance, cast-iron borings.

From what has been said above, it appears probable that the difficulties are not caused by the high conductivity of the coke, but by its tendency to be transformed to graphite. It should be possible to avoid this by designing the furnace so that the charge arrives at the electrodes correctly proportioned. The factors which determine this are the dimensions of the furnace hearth, which, again, determine the possibility of running with an even load by means of regulating voltage only, without adjusting the electrodes.

NECESSITY OF ADJUSTING ELECTRODES

This latter circumstance is of especial importance when smelting charges of low iron content in furnaces with relatively small hearths. Probably on account of this it has been found necessary at Tinfos to resort to regulation of the electrodes, because the amount of slag and iron is so large that the iron must be tapped frequently or else the electrodes raised. An even load may, however, be maintained by regulating the transformer voltage when operating this type of furnace in case the iron content of the charge is kept at about 60 per cent. Regulation of the electrodes, however, always causes a great loss of the rich gas which is one of the great assets of this furnace. It is easily possible to keep 20 to 30 tons of iron in an Electrometal furnace without experiencing any difficulty in keeping the power within normal limits by means of regulating the voltage.

The voltage, the current and the current density must be in a certain relation to one another in order to obtain

a heating area of correct size around each electrode. This fact may be visualized by comparing the electric current and its power of melting with the stream of water from a hose. The pressure of the water corresponds to the voltage and the volume of water per second to the current. Coke requires a higher temperature than charcoal to become active chemically, and this is obtained preferably with a high load, i.e., high current density.

UNIFORM GAS CIRCULATION ESSENTIAL

The distinguishing characteristic of the Electrometal furnace is the gas circulation, which, apart from the fact that it increases the reduction by the gases, distributes about one-third of the energy to the shaft. A more even temperature is thereby insured in the whole furnace, contrasting it favorably with other electric furnaces where the heat is unnecessarily concentrated around the electrodes. It is of the greatest importance that the gas circulation is adequately carried out, and for this reason the largest Electrometal furnaces are now provided with positive blowers, i.e., blowers delivering a constant volume, instead of fans with a constant pressure.

DATA ON A RUN WITH COKE

The only basis for comparison of results from furnaces of different types is the efficiency in utilization of electric energy. An Electrometal furnace, for instance, showed while operating with charcoal, an efficiency of over 80 per cent, and when operating with coke for four weeks, an efficiency of about 67 per cent. It is to be noted that the furnace in question was not designed for operation with coke, but was changed in such a way as experience had proved to be desirable for running with coke. The other types—Helfenstein, its modification Kepparberg, and Heroult-Haanel-Tinfos—did not reach a higher efficiency than about 50 per cent with the identical charge. However, the first two types can not be said to have passed the experimental stage, and the last mentioned furnace was operated with a load of about 500 kw.

The principal data from the run with coke in the Electrometal furnace are:

Average load, kw.	2,632
Voltage, volts	60
Current, amp.	14,000
Average production per day, metric tons.	23

After smelting was well under way the run was particularly quiet and even, without bridging of the charge or difficulties with the gas circulation, which facts also become evident from the following log:

Date	No. of Charges per Day	Date	No. of Charges per Day
17.....	52	23.....	52
18.....	52	24.....	53
19.....	53	25.....	57
20.....	57	26.....	51
21.....	55	27.....	55
22.....	52	28.....	52

MIXTURE OF COKE AND CHARCOAL SATISFACTORY

In connection with the main trial run with coke alone, the furnace was successfully run previously as well as subsequently with a mixture of coke and charcoal. The experience obtained naturally resulted in ideas regarding the use of coke alone; moreover, the test was important from an economic point of view. The substitution of 50 per cent charcoal corresponds to a lowering of the cost of the reducing agent of about 25 per cent (at peace-time figures).

The above-mentioned runs have, however, demonstrated that the Electrometal furnace is suitable for operation with coke, and I am of the opinion that a correctly designed furnace of this type at present should give the best results economically.

It is also my opinion that in order to obtain good results economically with smelting with coke, only large furnaces should be employed.

CONCLUSION •

I have made this contribution to the discussion about electric smelting with coke, because I think that certain considerations have been lost sight of, especially when judging the suitability of operating the Electrometal furnaces with coke. This type has been judged only from the negative results, which have been obtained in Trollhattan and Hardanger without considering the fact that the same difficulties which were experienced there also occurred when running with charcoal, and that these were overcome by suitable changes.

Swedish Wood Pulp Industry in 1919

The last two years of the war, 1917 and 1918, were very trying for the Swedish sulphite cellulose industry, as production had to be reduced considerably owing to the shortage of certain important materials and lack of customers. With the advent of peace the industry looked forward to at least a renewal of normal output if not an increase in business.

For the first half of 1919, however, this hope was not fulfilled, as tonnage was scarce and buyers were waiting for lower prices. This resulted in sulphite mills decreasing their production and running at only 64 per cent of normal capacity. By the end of the year, however, business had picked up somewhat.

	Production, Metric Tons	Normal Capacity, Approximate, Metric Tons	Per Cent
1913	699,937	700,000	100
1914	714,747	750,000	95
1915	742,000	760,000	97
1916	771,302	790,000	98
1917	554,966	825,000	83
1918	476,307	850,000	56
1919	581,167	850,000	69

The above figures show that in 1919 production was larger than in either of the two preceding years but still represented only about 69 per cent of the full capacity of the mills.

PAPER MARKET DISORGANIZED DURING THE WAR

During the last year of the war the paper market was disorganized both in Scandinavia and Canada. Paper, particularly in England and France, was offered freely in the first half of 1919 at prices so low that with the prevailing prices for cellulose the paper manufacturers in the countries named found it impossible to manufacture the corresponding sorts of paper at prices that would even approximate those at which the foreign paper was offered. Under such conditions it was not surprising that a restriction of imports was planned by the respective governments and that the impression grew abroad that Swedish quotations were unreasonably high.

SITUATION EXPLAINED TO ENGLAND AND FRANCE

Because of the conditions, the Cellulose Association sent two of its representatives to England and France to explain the situation to the authorities as well as the customers, and point out the causes of the high cost of production and the difficulties under which the

Swedish cellulose industry labored. The results of the work of this committee were apparently fruitful, as no measures were taken to regulate or ration the imports of pulp, although a proposal to such an end had already been formulated by the Allied Commission at a meeting in London. On the other hand, both England and France continued government control of the imports of paper in order to protect the domestic paper industry and enable it to resume operations on a large scale.

SUPPLY OF PAPER SHORT AND DEMAND LARGE

The summer brought a change in the paper market. The British paper manufacturers had obtained large orders under the protection of the restricted imports of paper, and had all their paper machines working again, and an increasing activity and a livelier demand were noticeable in the paper market of other countries also. By the end of the year it became evident that there was an acute shortage of paper and a veritable scramble for paper resulted.

During the latter half of 1919 the sulphite market developed along about the same lines as the paper market. In July the British paper manufacturers began to purchase paper pulp on a large scale and the sales increased until the end of the year. It was only during the end of the last month of the year that the paper manufacturers on the Continent commenced buying. They had been holding back in the hope that the promised shipments of Canadian pulp would ease the sulphite market in Europe. In the meantime it became evident that Canada could not deliver quantities of any importance, as the paper industry of the United States alone was able to absorb the entire Canadian surplus, and the Continental manufacturers then made haste to obtain supplies in Scandinavia. The rush of orders commencing in November, 1919, continued well into the first months of 1920, resulting in sharp increase in prices.

Factors Controlling Crude Oil Prices

A report on the causes of the advance in prices of gasoline, kerosene, fuel oil and other refined petroleum products, issued by the Federal Trade Commission June 1, states that the high price is due not because of a combination in restraint of trade, but to the varying conditions of supply and demand. The enormous demand for crude oil, the decline in stocks, the increased consumption of motor fuel by the ever-growing automobile industry, the increased cost of materials, labor and drilling, together with exportation to foreign countries and lack of transportation facilities in this country, have all been factors in the cost.

To conserve our supply of petroleum, which, although at present slightly on the increase, is estimated by geologists and oil experts as none too plentiful for our own growing needs, the Commission made the following recommendations to Congress:

1. Assurance of enough crude oil for home consumption in preference to exportation for foreign needs.
2. Further study in the wasteful methods of drilling and elimination by state legislation or otherwise of uneconomic methods of production.
3. A more extensive study in the possible utilization of shale oil.
4. Investigation regarding industrial and commercial conditions in the oil trade.

Legal Notes

BY WELLINGTON GUSTIN

Agreement With Promoters Not the Contract of the Corporation Subsequently Organized

The Circuit Court of Appeals, Fifth District, has affirmed judgment of the U. S. District Court for the Northern District of Georgia in the suit of George Beveridge against the Crawford Cotton Mills and others. This case involves the organization and promotion of the mills, and presents a lesson to organizers.

Beveridge alleged there was an agreement between himself and the co-defendants Ingle and Comer, for the formation of a corporation to take over and operate a cotton mill owned by Ingle, and likewise a mill on which Comer had an option. In pursuance of such alleged agreement the Crawford Cotton Mills was organized. Plaintiff claimed to be an expert in the handling and weaving of textile fabrics, and that, with certain other associates, he had in operation at Cedartown, Ga., a dyeing and finishing plant, and likewise a mill for the manufacture of duck; that, being desirous of forming a connection with other duck mills to supply material for his dyeing and finishing plant, he entered into an agreement with Ingle to form a corporation to take over the White City Manufacturing Co. plant, owned by the latter.

DETAILS OF THE AGREEMENT

This agreement, it is charged, was superseded by a new agreement, entered into with both Ingle and Comer, who held an option on two other mills, known as the Edwards mill and Edwards power plant. Under this agreement the Edwards properties were to be purchased for \$135,000 by the proposed corporation and such properties, together with the White City Manufacturing plant, to be acquired from Ingle for \$40,000, were to be bonded for \$145,000, out of which the price of the Edwards properties was to be paid, less \$20,000 cash to be advanced by Ingle and Comer. There was to be borrowed from a selling agent \$35,000 for operation. An expert engineer was employed, and he appraised the three properties at \$242,568.20.

CORPORATION TO BE FORMED

It was alleged that it was agreed to form a corporation, to be known as the Crawford Cotton Mills, with a capital stock of \$250,000, \$100,000 to be preferred stock and \$150,000 common stock; Ingle and Comer should receive preferred stock for the \$20,000 cash advanced by them, and that Ingle should receive \$40,000 of preferred stock for the White City plant and machinery and all merchandise and products on hand; that the common stock should be issued one-third to each of the parties, and they in turn should then transfer back to the company, to be held as treasury stock, all but \$45,000 of the common stock, each retaining \$15,000 of common stock, for which each should execute his note to the corporation; that Beveridge should be president, Ingle vice president, and Comer manager, each at a salary of \$10,000, out of which salaries their notes were to be paid at the rate of \$5,000 a year.

The contemplated corporation was formed, it is alleged, but the stock was not issued as per agreement; on the contrary, Ingle and Comer demanded that Beveridge pay at once \$15,000 in cash for his stock, which he refused to do, but for which amount he offered to execute his note as agreed previously. He further alleges that he was then presented with a subscription blank to be signed, subscribing for 150 shares of preferred stock, at \$15,000, and 500 shares of common stock at \$50,000, payment to be made on the call of the board of directors; that, being satisfied that this was a scheme to freeze him out, and that Ingle and Comer, constituting a majority of the board, would at once call upon him for the full amount of \$65,000, he declined to sign the subscription blank, stating that he was willing to subscribe for the stock on the conditions and terms which had been previously agreed upon, whereupon the stock in full was subscribed by Ingle and Comer and another, O'Neal.

FROZEN OUT, SAYS PLAINTIFF

It appears that the White City Manufacturing plant and the Edwards properties were all taken over by the corporation and bonds were issued as originally contemplated. Beveridge claimed that the corporation refused to let him have anything to do with its management and refused to pay him the salary as president agreed upon between the promoters. Beveridge alleged that his damages would amount to \$50,000, or other large sum, and prayed the court that Comer and Ingle be required to specifically perform the contract entered into, and that he be decreed the owner of 150 shares of the common stock upon payment of his note for the amount, and that he be declared the president of the corporation from the date of its organization at a salary of \$10,000 a year; that Ingle and Comer be decreed owners of such stock only as may have been subscribed and paid for by them, and that he have judgment against them for \$50,000 damages.

In an amendment to his petition for relief, Beveridge averred that he had made a trip to Philadelphia and New York, pursuant to the alleged agreement, and there secured the services of a competent selling agent, who advanced to the company \$35,000.

NO RELIEF, DECLARES COURT

The Court of Appeals affirmed the lower court, holding that even if plaintiff had a valid contract, his remedy was not for specific performance, but was an action in damages for its breach. It said there was no ground for equitable relief in plaintiff's claims, and further that there was a misjoinder of parties and causes of action. The court had neither authority to decree Beveridge owner of 150 shares of the company's stock, nor to declare him president of the corporation. He had no contract whatever with the Crawford Cotton Mills, and the alleged agreement was between him and the promoters of the corporation prior to its organization. The only claim he could have against the corporation, which is a distinct legal entity or individual from its promoters, is one for services rendered to it in the purchase of looms and in acquiring the sales agent, said the court.

Whatever remedy plaintiff had under his alleged agreement, if any, was at law for breach of contract, and his rights at law appear too vague and indefinite to sustain a recovery.

British Chemical Industry

FROM OUR LONDON CORRESPONDENT

London, June 7, 1920.

THE advent of the holiday season is having the usual effect upon the chemical industry and the past month has been distinctly quiet, though the general position is considered to be very satisfactory. The somewhat sensational reductions in the prices of metals, cotton and wool, together with the tail end of the wave of labor unrest, have had a temporary depressing effect, but the strong latent demand for most technical chemicals had a stabilizing influence on prices, which remain practically unchanged. Quicksilver has been a notable exception, certain stocks having been thrown on the market at a considerable sacrifice.

A REPRESENTATIVE MERCHANTS' ASSOCIATION

Under the name of the British Chemical and Dyestuffs Trades Association, the new organization foreshadowed in these columns* has now been formed and has met with a somewhat mixed reception owing to the attitude of studied aloofness which it has taken toward the original and less influential British Chemical Trade Association. The latter was originally formed by a number of the smaller firms together with two of the larger East India merchants, partly for patriotic reasons and partly, it is thought, for self-protection in regard to government restrictions and a large number of pending arbitration cases. The American Chamber of Commerce gave its support at a later date and there is no question that the association carried out valuable work at a critical time. The threatened existence of two rival associations is universally deplored and it is to be hoped that fusion will ultimately take place and that steps will be taken to arrange for friendly co-operation with similar institutions in the United States and elsewhere.

CHEMISTS INAUGURATE MASONIC LODGE

The consecration of what is believed to be the first lodge composed of analytical and manufacturing chemists took place recently at the Freemasons' Hall, its title being Radium Lodge No. 4031. The leading spirits in its formation were A. Gordon Graig, N. J. Bluman and Prof. W. R. Hodgkinson, C.B.E., formerly of the Royal Academy, Woolwich. The latter was appointed secretary.

COMMERCIAL DEVELOPMENTS

Anglo Spanish Tartar Refineries, Ltd., has been formed with a capital of about \$600,000 to develop the tartaric acid industry in Spain. Formed under the auspices of the Phoenix Chemical Co., which has successfully met part of the demand in this country, a new source of supply will presumably be available to meet next year's threatened shortage. In the nitrate field, the details of the Brunner Mond-Explosives Trades acquisition have now been announced. The capital of Synthetic Ammonia & Nitrates, Ltd., is about \$20,000,000, or twice that of Atmospheric Nitrogen & Ammonia Products, Ltd. (Claude process), referred to in my last article. The projected output of the Billingham factory is 100 tons of ammonia per day, capable of rapid expansion to 300 tons per day. Interesting features are the safeguards against interference by the owners of the Haber patents—by means of compulsory licenses on a royalty basis—and for the maintenance of the company

under British control. Explosives Trades, Ltd., is to erect the necessary plant for the oxidation of part of the company's ammonia to nitric acid for explosives manufacture and to the extent desired by the British Government. In view of the present great shortage of sulphate of ammonia, particularly for export account, these new developments of the synthetic process should be of far-reaching importance in stabilizing food supplies and incidentally in absorbing the surplus sulphuric acid production rendered available by the erection of war-time plants.

A British patent of considerable interest to the American chemical industry is that of Rossi, just published, No. 130,963, covering the extraction of potash compounds from leucites or feldspars, with simultaneous production of nitrogenous fertilizers. Rossi has found that the ordinary method of manufacturing cyanamide can be adapted to the treatment of potash-bearing rocks, the mixture of the finely ground rock with calcium carbide being heated in a stream of nitrogen in exactly the same way as in the cyanamide process, the heat of reaction being sufficient to enable considerable additions of potash-bearing rock, lime and carbon to be added to the raw mix. The potassium compounds may be either volatilized or left behind with the resulting complex nitrides to give compound fertilizers, and it is stated that the nitrogenous fertilizers are readily assimilable by the crops.

THE "POPE" OF THE BRITISH CHEMICAL INDUSTRY

The appointment of Sir William Pope to the presidency of the Society of Chemical Industry has been universally approved and the delay in making an announcement is comprehensible in view of the great responsibility attaching to the post at the present time. Sir William Pope is an ardent exponent of co-operation and federation among learned and scientific societies and has done valuable work during the war in regard to mustard gas and also in connection with various commercial developments. The Society of Chemical Industry had intended to hold its annual meeting next year in Canada, thus bringing before the whole body of its members the great developments in the chemical industrial field which have taken place during the war and since the armistice both in the United States and in the British Empire. Unfortunately it seems certain that this visit will have to be postponed and the appointment as president of the society of a man like Prof. R. F. Ruttan cannot materialize as yet. The reasons for this change in program are primarily financial, the society, in common with many other institutions of this kind, being faced with enormously enhanced charges for printing, salaries, etc., which are not adequately met by increased advertising revenue. A drastic increase in the subscription rates is probable and in the meanwhile the venue of the annual meeting next year will probably be in this country with a view to consolidating "the home front." Apart from his distinguished academic career, Sir William Pope is an ardent supporter of the new Chemical Industry Club. It may be apposite to mention here that members of the New York Chemists' Club visiting this country are *ipso facto* entitled to the privileges of membership of the Chemical Industry Club by notifying the secretary at 2, Whitehall Court, London S. W. 1. The shortage of hotel accommodation threatens to be very serious in London and American visitors should not overlook the residential facilities offered by this club.

*See CHEM. & MET. ENG., May 5, 1920, p. 828.

Recent Chemical & Metallurgical Patents

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Alkali Cyanides.—In a process in which an alkali cyanide is made from nitrogen, alkali-metal compound and carbon, and the cyanide is then converted into ammonia and alkali carbonate, which is used again, the alkali carbonate, before being used again, is purified from silica, alumina, etc., by treating with carbonic acid or other acid containing no element other than carbon, hydrogen, oxygen and nitrogen, or with lime. (Br. Pat. 136,772—1919. C. T. THORSELL and H. L. R. LUNDREW, Gothenburg, Sweden, Feb. 11, 1920.)

Obtaining Textile Fibers.—Woody vegetable material, such as the stalks and other parts of plants having a hard bast, such as the rind of ramie, trees, etc., is treated successively with two liquids which tend to react within the material, generating gas. A 20 to 40 per cent alkali solution, boiling or not, may be used, and subsequently a saturated solution of an ammonium salt, such as the chloride, the material being boiled therein until the ammonia gas is completely discharged. The material is finally washed with water, which may be boiling, and dried. Ammonia gas generated within the fibers tends to split away the woody material, laying bare the fibers. (Br. Pat. 136,804—1919. M. HOFSTE, Amsterdam, Holland, Feb. 11, 1920.)

Treating Slag.—Water, with or without steam or other gases, is poured or forced into or upon molten slag so as to form a foam sufficiently liquid to be poured into molds, in which it is cobbled so as to form porous bricks or insulating material. The product may be crushed or used as a filling for walls and the like. In an example, slag is heated in an electric furnace to a temperature of 1,400 deg. C. and poured in a continuous stream into a container lined with refractory material through an inlet formed in the lower part of the container. Above this inlet, one or more tuyeres are provided through which water is admitted, preferably under pressure, when the slag is on a level with or above the tuyeres. The water is added in a continuous stream, and is intimately mixed by means of a rotary stirrer mounted in the container, the stirrer being so constructed as to prevent an accumulation of solid slag on the tuyeres. The supply of water is regulated so that the temperature of the foam will be about 1,000 deg. C. At this temperature it is liquid and may be led through an overflow into molds. (Br. Pat. 136,818—1919. NORSKE AKTIESELSKABET FOR ELEKTROKEMISK INDUSTRI, Cristiania, Feb. 11, 1920.)

Alkali Valerates.—In the preparation of potassium valerate by the interaction of amyl alcohol with caustic potash according to the equation

the reaction is carried out in autoclave under such a pressure as will keep the amyl alcohol, which is employed in excess, in the liquid condition at the reaction temperature, a regulating device being provided for

the escape of the hydrogen. Caustic soda may replace the caustic potash. In the example, a mixture of amyl alcohol is heated to a temperature of 235 to 240 deg. C. under a pressure of 18 atmospheres. (Br. Pat. 137,064—1919. SOC. DARRASSE FRÈRES ET CIE, Vincennes, Seine, France, Feb. 25, 1920.)

Ferro-Tungsten-Chromium Alloys.—Ferro-tungsten-chromium alloys for use in high-speed steels are obtained from an aluminothermic mixture containing oxides or other compounds of tungsten and chromium in chemical combination with one another, or with compounds of another metal required in the alloy. Chromic di-tungstate for use in the process is prepared from a solution of sodium tungstate with chromium sulphate in the presence of soda ash. Additional tungsten required to increase the percentage in the alloy may be precipitated from the solution as ferrous tungstate, or it may be free from combination with another metal. The carbon may be added as carbide, or steel scrap, and the balance of the iron as forge scale. The high-speed steel may be produced in one operation, or the ferro-tungsten-chromium alloy may be separately produced and afterward added to the steel. (Br. Pat. 137,080—1919. H. L. SULMAN and W. B. BALLANTINE, London, Feb. 25, 1920.)

Preserving Yeast.—In order to preserve live yeast for use in the manufacture of fertilizers or cattle foods or for other purposes, without heating, desiccating or adding inorganic chemical compounds, it is mixed with peat or powdered peat moss or tanner's bark, wood fiber or fine sawdust, and vegetable charcoal, and the whole pressed. (Br. Pat. 137,131—1919. J. R. ROBINSON, Stockton-on-Tees, Durham, Feb. 25, 1920.)

Potassium Sulphate, etc.—Finely ground potassium bisulphate and potassium chloride are mixed intimately in theoretical proportions or with a small excess of bisulphate and heated to 300 to 350 deg. C., concentrated hydrochloric acid free from sulphuric acid, and potassium sulphate almost free from chloride being obtained. When a small excess of bisulphate is used, pure sulphate may be obtained, but some sulphuric acid is expelled and is condensed. For this modification, a second heating to 700 deg. C. is employed and the two operations may be effected in a salt cake furnace. The reagents may be treated with a little water, for instance by spraying, before the reaction, but the quantity should be such that the mass remains pulverulent. (Br. Pat. 137,296—1919. FABRIQUES DE PRODUITS CHIMIQUES DE THANN ET DE MULHOUSE, Thann, France, March 3, 1920.)

Acetic Anhydride.—Acetic anhydride is prepared by heating an intimate mixture of an acetate, such as sodium acetate, with a pyrosulphate, such as sodium pyrosulphate, preferably in the presence of a diluent, such as acetic anhydride or glacial acetic acid. The acetic anhydride is distilled off as formed. The sodium pyrosulphate used may be prepared by heating sodium bisulphate. (Br. Pat. 136,574—1919. H. DREYFUS, London, Feb. 11, 1920.)

Phthalic Anhydride.—Phthalic anhydride is produced by the treatment of nitronaphthalene with sulphuric acid, not necessarily the concentrated or fuming acid, in the presence of a metal such as iron or zinc commonly used for the reduction of nitro compounds. (Br. Pat. 140,051—1919. H. SASA, Tokyo, May 5, 1920.)

Synthetic Tanning Agents.—Synthetic tanning agents are prepared by condensing aromatic sulphochlorides with the alkali-soluble fractions of anthracene oil or soft pitch, and sulphonating the condensation products so obtained. According to an example, anthracene oil or a soft pitch distillate is extracted with dilute caustic soda lye, the extract is purified and condensed with toluene sulphochloride in benzene solution, the product is sulphonated with sulphuric acid monohydrate, and the sulphonic acid converted into its sodium salt. (Br. Pat. 137,323—1919. M. MELAMID, Breslau, Germany, March 3, 1920.)

Casting Aluminum and Its Alloys.—Metal molds for using in casting aluminum and its alloys are coated with a thin layer of aluminum preferably applied by painting or spraying with aluminum bronze, the mold being afterward slowly heated to 400 deg. C. to remove all traces of the medium. Prior to pouring, the mold is heated to from 550 to 700 deg. C. Cover may be similarly coated. (Br. Pat. 137,325—1919. METAL INDUSTRIE SCHIELE & BRUCHSALER, Hornberg, Baden, Germany, March 3, 1920.)

Production of Hydrogen.—In the production of hydrogen by passing gases containing carbon monoxide with steam over a catalyst and removing the carbon dioxide with lime, a series of alternate catalytic chambers and lime chambers is employed, the pipe connections and the absorption chambers being heat insulated, so that the process is effected without loss of temperature. Pressure may be employed. The gases may be passed through a heat exchanger at the beginning and at the end of the apparatus. (Br. Pat. 137,340—1919. H. E. F. ADAMS AND H. C. GREENWOOD, London, March 3, 1920.)

Extracting and Purifying Oils.—Oils, particularly cod-liver and other fish oils, are extracted and purified by water below 100 deg. C. in presence of a current of inactive gas, such as hydrogen, carbon dioxide, nitrogen, water vapor, or a mixture of these. The oil or material is boiled at about 75 deg. C. with water in a jacketed pan connected to a vacuum pump, so that the current of water vapor is produced within the charge; low temperature steam, mixed or not with inert gas, may be injected. The water used may be fresh, salt, acid or alkaline. (Br. Pat. 137,514—1919. P. M. HAYERDAHL, Bygdo, Norway, March 10, 1920.)

Recovering Volatile Solvents.—The vapors of volatile solvents are recovered from air with which they are merged, by absorption in "active" charcoal such as that used in respirators. The charcoal is afterward heated to drive off the solvent, and the vapors are led to a condenser. Duplicate absorption chambers are used to provide for continuous operation. (Br. Pat. 137,615—1919. L. A. LEVY, London, March 3, 1920.)

Treating Ores.—Iron sand or other fine ore is briquetted to facilitate subsequent smelting, by mixing it with bituminous matter and coking the mixture in shallow open trays divided into compartments of the size and shape of the required briquets. A weight is placed on top of each compartment, or a weight may be used which affects all the compartments simultaneously; or a power press may be applied to the material before or after the distillation is completed. Lime, salt, manganese, etc., may be mixed with the material before briquetting. (Br. Pat. 137,626—1919. H. G. HILLS and E. WHEELER, Cheshire, March 10, 1920.)

Acetic Anhydride.—In the manufacture of acetic anhydride by interaction between anhydrous sodium acetate and phosgene, acetic anhydride is employed as the medium into which the reacting bodies are simultaneously introduced. The sodium acetate is kept in slight excess, and the mixture is well cooled and agitated. When the reaction is complete, a portion of the reacting mixture is withdrawn and its acetic anhydride content removed by distillation in vacuo. The remainder of the reacting mixture is used to treat further quantities of sodium acetate and phosgene. (Br. Pat. 137,701—1919. E. P. LEACH and UNITED ALKALI Co., Liverpool, March 17, 1920.)

Cellulose.—In a process for the production of hemi-cellulose from highly lignified plants such as wood, and of cellulose or textile fibers that can be spun from slightly lignified plants, such as jute, manila, hemp, reed grass, typha, nettles, the materials are heated under pressure in a lye containing alkaline sulphite, and sulphides with or without easily decomposable alkalis, such as sodium carbonate or soaps of alkaline metals. (Br. Pat. 137,831—1919. C. A. BRAUN, Munich, Germany, Mar. 17, 1920.)

Purifying Sugar Juices.—In purifying thick beet and cane juices by means of sulphurous acid and lime, the thick juices are first treated to effect a separation of sugar by crystallization, and to obtain a sirup which contains more impurities and in which therefore the sulphurous acid has less tendency to produce inversion. Sulphurous acid may be passed into the sirup until it is acid. (Br. Pat. 137,849—1919. M. VON WIERNISZ-KOWALSKI, Leipzig, Germany, March 24, 1920.)

Phenol-Aldehyde Condensation Products.—Insoluble infusible products are obtained by the action of "pectinizing agents" upon phenol-aldehyde condensation products. According to examples, phenol is condensed with formaldehyde in the presence of slaked lime or sodium cyanide; baryta and strontia are also specified as suitable agents. The agent may be added in portions at the several stages of the condensation. The products may be used in the manufacture of varnishes, lacquers, paints, agglutinants, plastic materials, etc. (Br. Pat. 138,061—1919. L. JALOUSTRE, Z. KHEIFETZ and M. WARCHAWSKY, Paris, March 24, 1920.)

Cellulose Esters.—In the manufacture of solutions, varnishes and plastic masses from cellulose esters, for instance nitrocellulose, acetylcelluloses and nitro-acetylcellulose, the ester is dissolved or gelatinized by furfural or a homologue or derivative thereof. The furfural may be used alone or in conjunction with other solvents or diluents and softening or modifying agents may be added. In examples, plastic masses are obtained by kneading together acetylcellulose and alcohol; and a solution, by dissolving in furfural, acetylcellulose soluble in tetrachloromethane, and diluting the solution, if desired, with alcohol, benzene, or even water. (Br. Pat. 138,078—1919. G. BONWITT, Berlin, March 24, 1920.)

Carbazol.—In the isolation of carbazol from mixtures containing it by conversion into alkali carbazol, hydroxide of the alkali metal is added in the presence of a neutral solvent and at a temperature below the melting point of the alkali carbazol. Naphthalene is an example of a solvent which can be used at ordinary pressure; solvents of lower boiling point, such as toluene, may be employed under pressure. (Br. Pat. 139,981. BURT, BOULTON & HAYWOOD and F. D. MILES, London, May 5, 1920.)

Current Events

in the Chemical and Metallurgical Industries

Activities of the Manufacturing Chemists Association

At the recent annual meeting of the Manufacturing Chemists Association held in New York City, on June 9, Henry Howard, Chairman of the Executive Committee, submitted the report of his committee for the year.

The work of this committee during the last year has largely been connected with the chemical problems arising out of the war and the termination of hostilities, particularly the work of the Chemical Foundation, and reports on various bills.

CHEMICAL FOUNDATION ADVISORY COMMITTEE

The Executive Committee feeling that the work of the Foundation would be greatly aided by the co-operation on the part of chemical and other manufacturers offered their services to help bring this condition about, and suggested that this co-operation could best be obtained by the formation of an advisory committee.

Acting upon this advice the Chemical Foundation called a meeting of its stockholders, organized them into sections according to industries, each section choosing its committee, and this committee choosing its chairman. The chairman of the various section committees formed the advisory committee and met regularly once a month in the office of the Foundation. The committee considered the most important matter accomplished so far by the Chemical Foundation was the principal adopted that there will be no limitation as to who shall be given licenses under patents provided the licensees are bona-fide American concerns, and that the patents will be worked by them in good faith and not taken out for stock jobbing purposes.

In order to secure the widest distribution possible of stock holdings in the Foundation the holdings were distributed among 160 American manufacturers, and an effort is being made to increase this number, so that each stockholder will not hold over a thousand dollars worth of stock.

Of the various bills pertaining to the chemical industry introduced into Congress since the signing of the Armistice, the Committee considered the Longworth bill (H. R. 8078) by far the most important. This bill contained provisions for licensing the importation of dyestuffs in order to protect the dye industry in America from foreign competition, and the executive committee took active part in urging its passage. Representatives of the Association appeared before the Senate Finance Committee and presented oral arguments in favor of the bill. In addition a brief was prepared by a sub-committee, under the direction of the executive committee and submitted to the State Finance Committee.

The bill is still pending and with earnest effort it should be possible to have it advanced for consideration in the Senate in the next session of Congress. It is the general belief that a majority of the Senate are not unfavorable to the bill.

The pyrites tariff bill (H. R. 5215) provided for a duty on the importation of pyrites and other crude iron sulphide minerals of 15c. per unit of sulphur content or a duty of more than 100 per cent. The committee felt that the passage of this law would be highly injurious to the chemical industry of this country and fought against it with a result that it now seems certain that the bill will not be brought up for action.

PATENT OFFICE BILL

The passage of the bill to increase the salaries of the personnel of the Patent Office was at first urged, until at the last moment a rider was tacked on incorporating the whole of another bill (S. 3223) which was opposed by the committee. At first sight, the bill had for its apparent object the rewarding of government employees who made inventions, but the proposed legislation actually provided that the Trade Commission might acquire and develop inventions, not only of Government employees, but of other individuals or agencies, which meant that the Commission could receive patents from any or all inventors throughout the United States. Having received the patents from any source, it could collect fees and royalties for licenses in such amounts and in such manner as the President should direct.

Through the National Industrial Conference Board the executive committee brought this matter before the manufacturing interests of this country with the result that the objectionable bill was amended and its enactment held up for this session.

OTHER ACTIVITIES

In addition to the above the committee has had prepared by counsel an analysis of the Peace Treaty, to bring out its effects on chemical industry. It has also prepared a statistical report on foreign trade, and kept in touch, through its membership in the National Foreign Trade Council, with trade conditions in European and other foreign countries.

The Association was represented in the International Trade Conference which was held October, 1919, at Atlantic City, by several members of the American Committee, which conferred with chemical representatives from France and Italy. The one tangible result of this conference was the decision to form an International Chamber of Commerce. The organization meeting has been called in Paris during the latter part of this month and C. Wilbur Miller of the Davison Chemical Co. will attend as a delegate.

And last but not least the committee has taken up with the Bureau of Explosives such matters as standard tests for carboys, welded drums, carboy neck protectors, new types of carboy stoppers, transportation of niter cake, hydrofluoric acid and mixed acids.

The Washington office is maintained jointly by the Manufacturing Chemists Association, the National Fertilizer Association, and the Chemical Alliance, Inc. This office has turned out to be an especially valuable adjunct to the Association.

THE CHICAGO CHEMISTS' CLUB LOUNGE

Chicago Chemists' Quarters Completed

The house warming and first "ladies night" held on the occasion of the opening of the newly-furnished lounge in the Chicago Chemists' quarters at 315 Plymouth Court on the evening of June 23 was a complete social success. Seldom are such gatherings effected and the program carried out with just the proper note of informality without loss of dignity as was manifest at this function.

Nearly one hundred members with ladies enjoyed an informal dinner and songfest in the main dining-room. After dinner the guests were introduced to the lounge, where President William Hoskins, Dr. W. Lee Lewis and Frank M. DeBeers with their ladies formed the receiving line. An excellent musical program followed by dancing completed the evening. The accompanying photograph will give some evidence of the quiet tone of refinement in this new home for Chicago Chemists.

The organization is founded for purely social purposes with a personnel composed of leaders in chemical science and industry of the Chicago district. While the success of any such body is assured through the high character of the individual members, the outward manifestation is found in the quarters they establish, just as we judge a man by the interior of his home. The atmosphere of this place cannot fail to impress the future visitor with the genial nature of the Western chemists, and leave with him a pleasurable feeling in having crossed the threshold.

Paul N. Leech, chairman, with J. A. Hynes, W. Lee Lewis and Carl S. Miner form the House Committee for the club.

Committees for Chicago Convention, A. C. S.

The following roster of committees and their respective chairmen for the fall meeting of the American Chemical Society at Chicago, Sept. 7 to 10 inclusive, was confirmed June 19 by the convention executive committee (W. Lee Lewis, chairman; R. J. Quinn, secretary):

Finance, A. M. Taylor; publicity, C. H. Jones; excursions, H. McCormack; registration and information, Glenn H. Pickard; hotels, S. L. Redman; transportation, A. E. Schaar; program, J. A. Hynes; banquet, D. K. French; men's entertainment, H. N. McCoy; ladies' entertainment, Ethel N. Terry; Relation to other scientific societies, William Hoskins.

Regulations Concerning the Chile Nitrate Industry

A cablegram received from the American Embassy at Santiago, Chile, June 10, 1920, states that at a recent session of the nitrate association it was decided to extend the date of session to June 30. The scale of prices agreed upon for delivery of nitrate were as follows: June and July, 15s. 5d. (\$3.75) per Spanish quintal (101.4 lb); August, 15s. 11d. (\$3.87); November, 16s. 10d. (\$4.09); December to April, 17s. (\$4.14). A clause protecting buyers was passed providing that in case of reduction of price the reduction rates will favor the buyer for all nitrate, not paid for, which he is under contract to receive. This agreement is valid until April 30, 1921. No sales less than fifty tons will be made for exportation, and a surcharge of 6d. will be placed upon certain amounts (not specified) up to 100 tons. 4

Annual Meeting of the Pacific Division, American Association for the Advancement of Science

The annual meeting of the Pacific Division, American Association for the Advancement of Science was held in Seattle, June 17, 18, 19 and brought together a large and distinguished gathering of the West's foremost scientists. The University of Washington was the scene of the many successful conferences, symposiums and sectional meetings of the affiliated societies while excursions and entertainment were provided throughout the adjoining territory.

Twenty-five societies were affiliated with the Pacific Division of the A. A. A. S., among which are included three sections of the American Chemical Society—the California, Intermountain and Puget Sound. At a very interesting joint meeting of these three sections the following program was presented:

PAPERS PRESENTED AT SECTIONAL MEETINGS

"Ammonocarbonic Acid and Its Salts," by E. C. Franklin; "The Ratio of Invert Sugar to Sucrose in Relation to the Flavor of Storage Apples," by A. W. Barton; "Destructive Distillation in the Northwest, Including Low Temperature Distillation of Lignite and of Wood," by H. K. Benson; "Improvements in the Sand Test of Detonators," by W. M. Dehn; "Sympathetic Inks in Connection with the War," by F. H. Heath; "Selenium Mustard Gas," by W. L. Semon; "The Diffusion of Sea Water in the Seattle Canal System," by T. G. Thompson; "The Magnesite Industry in the Pacific Northwest," by G. E. Whitwell.

Dr. Franklin's paper was a discussion of one phase of the important work that he has been doing for many years at Stanford University in his study of the similarity between water and ammonia as solvents and between aqua and ammono acids, bases and salts.

Of particular interest to the chemical engineer were the discussions of destructive distillation. Dr. Benson has pointed the way to the Northwest in the utilization of low grade lignites through low temperature distillation.

SYMPOSIUMS PRESENTED AT GENERAL MEETING

Of the general sessions the most important were: The symposium on the animal and plant resources of the North Pacific Ocean, in which it was pointed out that further control was necessary to insure to Alaska the continuation of its present valuable salmon and whaling industries; the research conferences in which Dr. A. O. Leuschner and Dr. F. M. Padelford, Deans of the Graduate Schools of the Universities of California and Washington, respectively, called attention to the imperative need of additional provisions necessary to keep research men in the University at this time when industry is making such successful inroads upon their number, and the symposium on the Einstein theory of relativity, in which was presented the remarkable work of the various astronomical expeditions and stations in endeavoring to experimentally determine some of the constants mathematically deduced.

EXCURSIONS

Among the excursions provided and enjoyed those of special interest were the visit to the Everett Pulp and Paper Co. where the soda process is used in the manufacture of paper from resinous mill waste; the American Nitrogen Products Co. at La Grande where 10,000 lb. of sodium nitrite is manufactured daily by arc fixa-

tion of atmospheric nitrogen and subsequent absorption of the gases by solution of soda ash; the Snoqualmie Falls, and the Snoqualmie Falls Lumber Co.

These falls, which have a depth of 268 ft., provide the hydro-electric power to operate the Snoqualmie Falls Lumber Co.'s mills. This company is unique in its application of electricity to its logging operations. It operates one mill exclusively for Douglas fir, another for hemlock and cedar, and also an electric shingle mill which has a total capacity of 500,000 ft. of lumber per day.

The 1921 meeting of the Pacific Division will be in or near San Francisco.

Accountants Association Formed

The Industrial Cost Accountants Association was organized in Chicago on the 18th of June by representatives of leading manufacturers in various lines of industry.

The object of the new association is the standardization of accounting and cost terminology and the adoption of standard governing principles; the promotion of active co-operation and interchange of average experiences between representatives of manufacturers engaged in similar activities; the education of the members and their business associates in the complex economic problems of industry; to assist standardization committees in each line of industry in establishing uniform accounting and cost practices; to act as a clearing house in distributing to all members the development in cost practices to the end that uniformity, once established, may be maintained.

MEMBERSHIP

Applicants for membership must be placed in nomination by an industrial firm or corporation, or trade organization, which must certify that the proposed member is either the owner, an officer, or a permanent employee actively engaged in the supervision of costs in such firm or corporation, or trade organization. Persons are not eligible to membership who are engaged professionally in the public practice of cost accounting on their own account, or in the employ of others so engaged. The annual dues are \$25 payable in advance.

The industries represented in forming the association were the electrical, tanners (13 divisions), gear, brick, confectioners, concrete pipe, air brake, sand and gravel, farm operating equipment, cotton fabric, baking, concrete products, laundry, gas engine, and window glass manufacturers.

OFFICERS

M. F. Simmons of Schenectady, N. Y., supervisor of costs for all General Electrical Company interests, was elected president of the association. C. H. Smith of Wilmerding, Pa., director of clerical operations of the Westinghouse Air Brake Company interests, was elected first vice-president. Roland H. Zinn of New York, chief of the cost accounting bureau of the Tanners' Council, was elected second vice-president. A. A. Alles, Jr., of Pittsburgh, secretary of the Fawcus Machine Company and treasurer of the Schaffer Engineering & Equipment Company, was elected secretary-treasurer of the new organization.

Headquarters of the association will be in Pittsburgh, at the office of the Secretary-Treasurer, 1501 Peoples Bank Building.

Boston University Establishes Branch in Havana, Cuba

The subject of foreign trade has received increasing attention since the war, and its problems are being met by numerous schools and colleges in their offering of courses which are intended to train the students for effective work in the commercial world. A recent important development in this field is the establishment in Havana, Cuba, of a Spanish-American branch, of the College of Business Administration incorporated in Boston University.

Dean Everett W. Lord states that the courses of the Havana branch parallel those given in Boston and lead to the same degree, bachelor of business administration. Courses are given in Spanish, with the use of textbooks prepared especially for Boston University classes. Students attending the College of Business Administration located in Boston may spend the sophomore or junior year in Havana without change of courses and without loss of time, thus having opportunity to perfect their knowledge of Spanish and to become intimately acquainted with Spanish-American life and customs. In the same way Cuban students, after a year or more at the Havana branch, may transfer to Boston to complete their course. A board of guarantors representing the leading banks and business houses of Cuba are lending their co-operation.

Endorsement of Federated American Engineering Societies by Engineering Council

At its regular meeting June 17, 1920, after hearing a report on the Organizing Conference, Engineering Council took the following actions:

Voted: that Engineering Council heartily endorse the plan of organization of the Federated American Engineering Societies and the American Engineering Council, adopted by the Organizing Conference of technical societies in Washington June 3 and 4, and authorize its Executive committee to proffer and perform on the part of Council such assistance as may be practicable in completing the work of the Organizing Conference and of the Joint Conference Committee of the Founder Societies in establishing the American Engineering Council.

Voted: that Engineering Council authorize its Executive Committee to deal with any question of co-operation with the Joint Conference Committee of the Founder Societies, relating to the permanent organization of the Federated American Engineering Societies, which may come up during the summer.

Voted: that the Secretary be instructed to invite to future meetings of Engineering Council delegates of the societies participating in the Organizing Conference in Washington, June 3 and 4, and editors of technical journals who may be interested.

Fall Meeting of the American Electrochemical Society

At the invitation of the members of the American Electrochemical Society residing at Cleveland, Ohio, supplemented by the cordial support of the local section of the American Chemical Society and the Engineers' Club, the Fall meeting of the American Electrochemical Society will be held in Cleveland, Thursday, Friday and Saturday, Sept. 30, Oct. 1 and 2. Headquarters will be at the Hotel Statler. The Engineers' Club will extend the courtesy of the use of its club rooms on the top floor of the hotel. Plans are under way which give promise of a meeting of exceptional interest. Dr. N. K. Chaney of the National Carbon Co., is in charge of local arrangements.

Personal

MARSTON T. BOGERT, professor of organic chemistry, Columbia University, New York, has declined President Wilson's appointment as a member of the U. S. Tariff Commission.

Prof. HENRY A. BUMSTEAD, director of the Sloane Physical Laboratory, Yale University, has been elected chairman of the National Research Council for the year beginning July 1.

FOSTER A. BURMINGHAM, formerly at the Pittsburgh station of the Bureau of Mines, is now a research chemist with The Brown Co., Berlin, N. H.

ARTHUR L. DAVIS, formerly of the Fixed Nitrogen Laboratory, American University, Washington, D. C., is now research chemist with the International Coal Products Corp., Newark, N. J.

E. P. DILLON, general manager of the Research Corporation, New York, has just recently returned from an extended Western trip in which he visited various Cottrell installations in the far West.

Dr. RUDOLF GAHL sailed on June 30 for Peru, where he will conduct some metallurgical investigations for the Cerro de Pasco Copper Co.

JAMES C. GRAY, senior member of the law firm of Gray, Thompson and Rose, Pittsburgh, Pa., has been elected president of the Standard Chemical Co.

J. C. INGRAM, of the American Cotton Oil Co., has been promoted to take charge of a new development department recently created by the American Cotton Oil Co. and associated corporations.

D. O. JONES, in charge of the research laboratory of the Armour Fertilizer Works, Chicago, has resigned to accept a position with the Newport Chemical Works, Carrollville, Wis.

PAUL KESTNER has been awarded the medal for the year 1920 by the Council of the Society of Chemical Industry, (London) in recognition of his distinguished services to the chemical industry. He was one of the chief founders and first president of the Société de Chimie Industrielle in France, which was established in 1917. Among his notable achievements are the use of forced draughts in acid towers, automatic acid elevators, the climbing film evaporator, the scaleless water-tube boiler and other inventions in connection with beet sugar manufacture.

Dr. R. B. MOORE, chief chemist of the Bureau of Mines, and Dr. DORSEY LYON, its supervisor of station, will leave in the near future for the South to look over the possibilities of several sites which have been suggested for the new non-metallic experiment station which is to be established by the Bureau of Mines.

IRVING E. MOULTROP of Boston, at the meeting of the Trustees of the United Engineering Society, was elected as a trustee of the American Society of Mechanical Engineers and a member of the Engineering Foundation Board, to fill the vacancy caused by the death of E. Gybbon Spilsbury.

PAUL S. NICE, consulting chemist of Denver, Col., has returned after spending a few weeks in the East on a business trip. He was recently appointed engineer of tests for the Denver and Rio Grande R.R.

G. G. SWARD, duPont scholar in chemistry 1919-1920, whose graduate work was done in physical chemistry and who received the degree of Master of Science at the June commencement, has been appointed to a fellowship in the U. S. Bureau of Standards, Washington, D. C., where he began on July 1.

H. M. TRUSLER has accepted an appointment as chemist with the Proctor and Gamble Co. in their Cincinnati laboratory.

R. C. WELLS, of the chemical division of the U. S. Geological Survey, will examine some of the deposits of natural soda in the Western states during the summer.

CHARLES SPENCER WILLIAMSON, dean of the Medical School, University of Illinois, spoke before the Chicago Chemists' Club, June 22, on "Some Phases of Modern Medicine."

Current Market Reports

The Non-Ferrous Metal Market

New York, July 5, 1920.—Copper consumers are buying from spot to the end of the year, sales amounting to some 20,000,000 lb. last week in the outside market, at 18@18.50c. Tin declined slightly, but lead and zinc remained firm.

	Cents per lb.
Copper, electrolytic.....	18 00@19 00

The Iron and Steel Market

Pittsburgh, July 2, 1920.

The coal car priority accorded the coal mines by the Interstate Commerce Commission order, which got into actual and general operation June 22 or 23, facilitates the production of pig iron and steel, but not its distribution. For the general good of the country the order is a good thing, but to the iron and steel producing industry it is not, directly at least, a good thing, for what the industry has needed of late is not heavier production but better facilities for shipping the product. The order increases the production and movement of coal, in which the iron and steel industry benefits, but it decreases the supplies of open top cars for shipping pig iron and steel products. As commonly applied the order includes high side gondolas in addition to drop bottom cars, which according to one definition are what are distinctly "coal cars," and as the steel industry ships fully 75 per cent of all its products in open top cars its supplies

are naturally decreased. Even cars that are received by mills with loads are sometimes taken out empty, to go to the coal mines, the mills not being permitted to load them.

COAL MINES HAVE CAR PRIORITY

A common expectation is that within a week or so from this time the coal mines will be so well supplied with cars that the railroads can relax their efforts. While the order calls for a 100 per cent car supply to coal mines, it is well recognized that the average coal mine will be unable to load cars to the extent of 100 per cent of ratings, for eventually an increase in car supplies would uncover a labor shortage, or, if no labor shortage were uncovered then a lack of orders would be uncovered. The ratings are so high that shipments at rating would soon surfeit the country with coal.

Motor trucking of steel from mills in the Pittsburgh district has been increasing, and a rough estimate would be that at the present time from 2,000 to 4,000 tons of steel per working day is leaving mills in this district by truck. Most of the movement is to dealers and manufacturers in the Pittsburgh district, but there is some to railroad sidings removed from the mills, where cars may be had for loading to distant points, and there is a relatively small proportion of the steel that is being trucked long distances. The estimate just given refers only to the movement of steel to regular customers of mills having contracts and who in ordinary times get their steel by rail, and not to the trucking from warehouse that is customarily done.

DEPARTMENTS CLOSING

Not a few departments of large plants, and here and there a whole plant, either closed July 1 or will close at the end of this week, chiefly because of congestion of finished product. The disposition to close is in some instances emphasized by the moral effect the closing will have upon workmen who have been indisposed to show their normal or pre-war efficiency. In several instances departments are closed because other departments have fallen behind them, the object being to reduce the quantity of material in process. In other instances the object is to allow steel to accumulate in convenient form, as when finishing mills are closed and ingots, blooms, billets and sheet bars are accumulated, these forms admitting of convenient stocking with maximum tonnage for the space available. In some cases it is recognized that the piling of finished material at mill, against the orders of customers, has reached such a point that the customers may not want all the material at the later time at which it may become possible to ship it, there being no evidence that the consumptive requirements are increasing at this time.

There is no means of determining, or estimating with any closeness, the amount of finished steel that now lies at mill awaiting shipment. Probably 2,000,000 tons would be regarded as a low estimate, for some observers are disposed to place the total at 3,000,000 tons or more. In other terms, one might say that the accumulation is not less than one month's production at the average rate of production obtaining in 1912 and 1913, the two best tonnage years before the war, nor more than the equivalent of one month's full production at the present capacity, which is about 50 per cent greater than the capacity just before the war and about 70 per cent more than the actual production, on an average, in 1912 and 1913.

Obviously such an accumulation of steel is a serious matter. If it were shipped out suddenly, being cleared off in a period of say two months while current production were shipped at the same time, it would undoubtedly give some buyers altogether too much steel. Rail conditions are not at all likely to permit of the accumulation being moved off in any short period, but if so, then some of the steel will eventually reach customers too many months later than the time for which they specified it that it may be quite useless, the need having passed.

MARKETS QUIET

All branches of the general market are quiet, except for some insistent buying of small quantities of coke and pig iron, sending prices upwards again. Connellsville coke for spot shipment has brought as high as \$18 per net ton at

ovens for both furnace and foundry grade, probably the record high in the history of the industry. Basic iron, which as noted in last report had advanced to \$44, valley as minimum, has sold in a 2,000 ton lot for rather prompt shipment at \$45, which possibly may now be found to be the minimum for any delivery. Bessemer remains quotable at \$44 for large lots and \$45 for small lots, while foundry stands at \$45, valley, there being no demand except for small prompt lots.

The prices which several of the large independent steel interests have been quoting for three or four months past, including 3c. for bars, 3.10c. for shapes and 3.25c. for plates, are unchanged. There is little buying at these prices, but there is no particular pressure on the part of would-be buyers for reductions, since the common attitude of buyers is that they will buy only what they must have, paying the price asked, and will not buy any more on any terms. As long as the independents quote their higher prices the Steel Corporation experiences no difficulty in selling on contract the tonnage it is willing to allot to regular customers.

FERROALLOYS

Prompt ferromanganese continues easy at not much above the contract price of \$200, delivered, still quoted for second half. Spiegeleisen is \$72.50 to \$75, furnace, for prompt or future. Electrolytic ferrosilicon is quite inactive, the market being nominally about \$78 to \$80, delivered, for 50 per cent, and about \$150 for 75 per cent. Bessemer ferrosilicon remains at \$62.50 for 10 per cent, \$65.80 for 11 per cent and \$69.10 for 12 per cent, f.o.b. furnaces at New Straitsville and Jackson, Ohio.

The Chemical and Allied Industrial Markets

New York, July 2, 1920.

The continued dullness in these markets remains unbroken. Buying interest on the whole has been indifferent except on some of the more desirable items the scarcity of which however prevents any activity worth mentioning. In investigating the *sodium salts* market it has been found that in general all grades are at least scarce and some unobtainable and that transportation difficulties are in a large part responsible for this condition. Producers are sold up on *sodium bicarbonate* and will not have any to offer for at least three months and the spot market is in the same condition with the average ranging between \$2.50@3.00 per cwt. for what little material that changed hands. The shortage of niter cake has held up the production of *sodium bisulphite* that quotations of 6c. per lb. are merely nominal as there is no material being offered.

Sodium chlorate and *cyanide* are probably in better condition than the other items in this class, *chlorate* being available on contract at 10@11c. per lb. while *cyanide* is being delivered at 25@26c. per lb. *Sodium nitrite*, which had such a sensational rise a few weeks ago, is quiet and very little demand is being exhibited; with the recent importations of this material there is now an adequate supply which is being sold around 17c. per lb. *Caustic soda*, *soda ash* and *sal soda* which have consistently been referred to as the "scarcer items," remain under that heading, although there have been some offerings of *caustic* made around 6c. per lb.; the present weather conditions are probably the reason back of this offering as this material cannot be stocked in warm weather.

COAL TAR PRODUCTS

No change has been noted in the weak position of the coal tar products market as reported last week. If an accurate list of sales of the two periods could be compared the latter probably would show more declines than rises in prices, but the volume of business is so small that a comparison of this kind would not sufficiently prove the point that this market is on the downward trend. *Aniline oil* is easier and sales have come down to 32@38c. per lb. against a previous level of 35@40c., and in sympathy the *salts* are lower also, being listed at 40@45c. compared with 42@50c. per lb. of the previous week. *Beta-naphthol* is the possible exception in this market and it is now hard to obtain the sublimed grade under 90c., while the average price is nearer \$1 per lb. The technical grade is also scarcer with prevailing prices ranging from 70@90c. per lb.

NAVAL STORES

This branch is marking time with the buyer waiting for still lower prices, which will probably come as the past week has shown a still further decline. Supplies are in a much better condition and arrivals from the Southern market are ample to take care of the local trade, which at present is light. *Turpentine* is receding to its former level, reaching as low as \$1.75 per gal., which was about the average price of six months ago. However, business has not resumed its former stride and exporting, which comprises a large part of this trade, is dull.

Baltimore, Md., June 30, 1920.

Fertilizer manufacturers in this section have been handicapped during the last week on account of an "outlaw" railroad strike resulting in an embargo not only on incoming but on outgoing shipments as well, and practically no complete fertilizer has been shipped out during the last week, although the season for wheat fertilizers is now on. It is with difficulty that the railroads are handling perishable food stuffs, but it is hoped this condition will be remedied in another week at the most.

Acid Phosphate.—The market continues firmer with practically no resale lots offering and producers well sold up for the summer months, and unable to take on but a very limited tonnage for movement by cars. The nominal quotation for 16 per cent grade, in bulk, is now \$20 per ton f.o.b. cars, although some sales have been made during the past week as high as \$22 per ton, in buyer's bags, f.o.b. cars Baltimore. Run of pile testing 17 to 18 per cent is quoted from \$19 to \$19.50, basis 16 per cent A.P.A., quantity and shipments subject to seller's approval and car supply permitting. Phosphate rock remains scarce, and there does not seem to be any relief in sight for some time to come, and even though shipments should come out from the mines in better volume during the next month or two, it is not anticipated that this will have any material bearing on the market, as an enormous tonnage will be required for next spring, and stocks of both acid phosphate and rock are running so low that the manufacturers will have to bend every effort to secure supplies of phosphate rock in order to enable them to take care of their trade next spring.

Blood and Tankage.—There has not been any change in conditions recently surrounding this material, but is significant that producers are not pressing their packing house byproducts on the market, and are holding firm at their views ranging from \$7.75 and 10c. to \$8 and 10c. f.o.b. Eastern shipping points, according to test and condition of the material.

Nitrate of Soda.—The market continues firm and August to October arrivals are quoted at \$3.90@3.95, November to December, \$4@4.05, and January to April, \$4.10@4.15 ex vessels Baltimore, and sellers claim that based on the present sterling exchange rate these prices figure lower than cost of importation based on the market in Chile.

Potash.—There have been no recent arrivals, and on account of the sold-up condition of the domestic producers, spot stocks are held firmly at \$2.65@2.75 basis 80 per cent for muriate, \$2.25@2.30 per unit for manure salt, and \$2.35@2.50 for kainit. Even at these prices there is only a limited tonnage available, and with the prospect of no heavy arrivals during the summer months when the demand is comparatively light, it looks as though present quotations on spot stocks will be maintained. As yet no schedule of import prices on Alsatian potash has been announced, but these are expected momentarily. In the meantime, but few of the manufacturers have covered for their next season's requirements.

Fish Scrap.—Weather conditions during the past week have been unfavorable for the catch of menhaden fish in the Chesapeake Bay, and while quotations remain unchanged at \$7.50 and 10c. for the machine dried unground scrap and \$6.25 and 50c. for the acid scrap f.o.b. fish factories, some of the producers are not inclined to take on further business at these levels, anticipating a higher market will rule later on more in line with animal ammoniates.

Nitrobenzol.....lb.	40 -	45
Nitro-naphthalene.....lb.	40 -	50
Nitro-toluol.....lb.	18 -	20
Ortho-aminodiphenol.....lb.	3.25 -	4.25
Ortho-dichlor-benzol.....lb.	15 -	20
Ortho-nitro-phenol.....lb.	80 -	1.25
Ortho-nitro-toluol.....lb.	35 -	45
Ortho-toluol.....lb.	2.50 -	3.00
Para-aminodiphenol, base.....lb.	2.50 -	3.00
Para-aminodiphenol, HCl.....lb.	1.08 -	1.12
Para-dichlor-benzol.....lb.	1.50 -	1.55
Paranitraniline.....lb.	1.35 -	1.50
Para-nitro-toluol.....lb.	2.60 -	3.00
Paraphenyl-nediamine.....lb.	2.00 -	2.50
Paratoluidine.....lb.	65 -	75
Phthalic anhydride.....lb.	12 -	20
Phenol, U. S. P., drums (dest.), (240 lb.).....gal.	2.00 -	3.50
Pyridin.....lb.	4.25 -	4.90
Resorcin, technical.....lb.	6.25 -	6.75
Resorcin, pure.....lb.		

Salicylic acid, tech., in bbls. (110 lb.)	lb.	\$0.50	—	\$0.52
Salicylic acid, U. S. P.	lb.	.50	—	.60
Salol	lb.	—	1.00	—
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.25	—	.31
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19	—	.24
Sulphanilic acid, crude	lb.	.32	—	.35
Toluidine	lb.	1.70	—	2.50
Toluidine, mixed	lb.	.45	—	.55
Toluol, in tank cars	gal.	.28	—	.32
Toluol, in drums	gal.	.29	—	.32
Xylidine, drums, 100 gal.	lb.	.50	—	.65
Xylol, pure, in drums	gal.	.37	—	.45
Xylol, pure, in tank cars	gal.	.35	—	.45
Xylol, commercial, in drums, 100 gal.	gal.	.37	—	.45
Xylol, commercial, in tank cars	gal.	.23	—	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark	lb.	\$0.36	—	\$0.39
Beeswax, refined, light	lb.	.39	—	.40
Beeswax, white pure	lb.	.63	—	.68
Carnauba, No. 1 (nominal)	lb.	1.00	—	1.25
Carnauba, No. 2, regular (nominal)	lb.	.85	—	.88
Carnauba, No. 3, North Country (nominal)	lb.	.43	—	.44
Japan	lb.	.21	—	.22
Montan, crude	lb.	.23	—	.25
Paraffine waxes, crude match wax (white) 195-110 m.p.	lb.	.09	—	.091
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.093	—	.10
Paraffine waxes, refined, 118-120 m.p.	lb.	.11	—	.121
Paraffine waxes, refined, 128-130 m.p.	lb.	.14	—	.15
Paraffine waxes, refined, 133-135 m.p.	lb.	.16	—	.17
Paraffine waxes, refined, 135-137 m.p.	lb.	.171	—	.181
Stearic acid, single pressed	lb.	.25	—	.26
Stearic acid, double pressed	lb.	.26	—	.27
Stearic acid, triple pressed	lb.	.27	—	.28

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940	gal.	\$1.80	—	—
Pine oil, pure, dest. dist.	gal.	1.60	—	—
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.48	—	—
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.35	—	—
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.	.85	—	—
Pine tar, ref., thin, sp. gr. 1.080-1.960	gal.	.36	—	—
Turpentine, crude, sp. gr. 0.900-0.970	gal.	1.75	—	—
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990	gal.	.35	—	—
Pinewood creosote, ref.	gal.	.52	—	—

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.	280 lb.	\$17.50	—	\$18.00
Rosin E-I	280 lb.	18.50	—	19.75
Rosin K-N	280 lb.	20.00	—	21.00
Rosin W. G.-W. W.	280 lb.	21.25	—	23.00

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

California

SACRAMENTO—The City Comrs. will receive bids about Aug. 15 for the construction of a filtration plant, cost, \$1,618,000. Plans include an intake, pier and conduits, \$155,000; filters, head house and pump, \$225,000; filtered water basin, \$115,000; coagulating basins, \$190,000; coagulating house, \$75,000, etc. M. J. Desmond, city clk. C. J. Hyde, engr.

Connecticut

BRIDGEPORT—The Cave Welding & Mfg. Co., 303 Center St., has awarded the contract for the construction of a 1-story, 42x93-ft. mill addition to welding plant on Center St., to Canning & Leary, Harris Bldg., New London. Estimated cost, \$18,000.

District of Columbia

WASHINGTON—The Bureau of Yards & Docks, Navy Dept., received the only bid for additions and alterations to the Aeronautical Engine Testing Laboratory, here, from Hyde & Baxter, 711-13th St., N. W., \$14,990. Noted June 16.

Georgia

LA GRANGE—Swift & Co., United States Navy Yard, Chicago, has awarded the contract for the construction of a 1-story, 200x350-ft. fertilizer plant, to George Johnson & Son. Estimated cost, \$250,000.

Indiana

VALPARAISO—The McGill Metal Co. plans to build a factory for the manufacture of bronze die castings. Estimated cost, \$100,000. Charles Meier, engr.

Iowa

LAWLER—The Bd. Educ. plans to convert grade school into a high school. Chemical and physical laboratories will be installed in same. Estimated cost, \$100,000. Frank Tustison, 355 Auditorium Bldg., Minneapolis, Minn., engr. Jacobson & Jacobson, Owatonna, Minn., archts.

Maryland

SPARROWS POINT—The Bethlehem Steel Co. is having plans prepared for the construction of a 2-story, 48x140-ft. hospital. Laboratory equipment will be installed in same. Estimated cost, \$150,000. J. E. Sperry, 409 Calvert Bldg., Baltimore, archt.

Massachusetts

HOLYOKE—J. & W. Jolly, Inc., South East St., has awarded the contract for the construction of a 2-story, 100x100-ft. foundry to the Casper Ranger Constr. Co., Bond St. Estimated cost, \$75,000.

LOWELL—The Saco-Lowell Shop, 77 Franklin St., Boston, has awarded the contract for the construction of a 1-story, 130 x 140-ft. foundry on Walker St., to D. H. Walker, 529 Dutton St. Estimated cost, \$100,000.

WILLIMANSETT—The New England Tire & Rubber Co., Springfield, is having plans prepared for the construction of a large factory for the manufacture of tires and tubes, here. F. H. Callahan, pres.

Minnesota

JORDAN—The Bd. Educ. has awarded the contract for the construction of a 2-story, 67 x 110-ft. high school, to the Harker Constr. Co., 638 Builders' Exch. Bldg., Minneapolis. A chemical laboratory will be installed in same. Estimated cost, \$100,000. Noted May 19.

MINNEAPOLIS—The State Bd. of Control, State Capitol, St. Paul, received bids

for the construction of a 3-story addition to the chemistry building at the University of Minnesota, from the Gauger-Korsmo Constr. Co., 301 Endicott Bldg., St. Paul, \$225,994; James Peterson, 3152 Tenth Ave., S., \$247,800; J. & W. A. Elliott, 906 Lumbar Exch. Bldg., \$254,725.

Missouri

ST. LOUIS—The St. Louis Malleable Casting Co., 7300 North Couduit Ave., is building additions and improvements to its present plant. Estimated cost, \$500,000.

New York

FALCONER—The Jamestown Malleable Products Corp., Jamestown, plans to build a 400x400-ft. malleable iron foundry. Estimated cost, \$300,000.

MARCY—The State Hospital Comn. will soon receive bids for the construction of a sewerage and water supply system including filter beds, chlorinating apparatus, settling tank, chlorinating building, etc., for the Utica State Hospital here.

SYRACUSE—The Atmospheric Nitrogen Corp., Milton Ave., has awarded the contract for the construction of a 1-story atmospheric nitrogen plant on Willis Ave., to the J. G. White Eng. Corp., 43 Exch. Pl., New York City. Estimated cost, \$500,000.

North Dakota

HANKINSON—The Bd. Educ. plans to build a 2-story, 65x130-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$135,000. Terry Schulte Eng. Co., 484 Endicott Bldg., St. Paul, Minn., engr. Buechner & Orth, Schubert Bldg., St. Paul, Minn., archts. Noted April 14.

Ohio

AKRON—The S. & O. Engraving Co., 330 South High St., has awarded the contract for the construction of a 2-story, 40x150-ft. office and laboratory building on South High St. to the Carmichael Constr. Co., 524 Hamilton Bldg. Estimated cost, \$75,000. Noted March 17.

CHAGRIN FALLS—The Adams Bag Co. is having plans prepared for the construction of a 3-story paper mill extension. Estimated cost, \$100,000. Ernest McGeorge, 1900 Euclid Ave., Cleveland, archt. and engr.

CLEVELAND—The city has awarded the contract for 23 hydraulic operated sluice gates for the easterly sewage treatment plants, to the Coffin Valve Co., Wade Bldg., G. R. Gascolgne, City Hall, engr.

Pennsylvania

HORRELL (Canoe Creek P. O.)—The Standard Powder Co., Philadelphia, has purchased a 700 acre site here and will build twenty-five 1-story buildings, each to be used for one step in the manufacture of powder. Estimated cost, \$1,000,000. Work will be done by day labor.

JEANETTE—The Amer. Window Glass Co., Farmers Bank Bldg., Pittsburgh, has awarded the contract for the construction of a 1- and 2-story furnace building, to the Hughes-Foulkrod Co., Oliver Bldg., Pittsburgh. Estimated cost, \$300,000.

Tennessee

KINGSPORT—The Grant Leather Corp. is building a 2-story, 275x500-ft. factory. Estimated cost, \$300,000.

Texas

PLANO—The city has awarded the contract for the construction of 2 sewage disposal plants equipped with chlorinators, etc., to Dalton & Campbell, 1915½ Main St., Dallas, at \$31,254.

Virginia

RICHMOND—The Baughman Stationery Co., 1320 Broad St., West, is having plans prepared for the construction of a 2-story, 173x227-ft. factory on Marshall and Graham Sts. Estimated cost, \$200,000. Carneal & Johnson, Chamber of Commerce Bldg., archts.

Washington

WENATCHEE—The city has awarded the contract for the construction of a filtration and pumping plant, to the California Filter Co., Spokane. Estimated cost, \$60,000. Noted May 26.

Wisconsin

MILWAUKEE—The Amer. Metal Products Co., 671 Kinnickinnic Ave., will soon receive bids for the construction of a 1-story, 80x200-ft. machine shop and foundry on Burnham St. Noted June 30.

MILWAUKEE—Scott & Mayer, archts., Colby Abbott Bldg., will soon award the contract for the construction of a 2-story, 70x100-ft. varnish factory and a 60x112-ft. warehouse on Lake St., for the Patton Paint Co., 213 Lake St.

Quebec

THREE RIVERS—Lafleur & McDougall, 107 St. James St., Montreal, will soon receive bids for the construction of a steel plant on Normand Blvd. Estimated cost, \$750,000.

Ontario

TILLBURY—The Tillbury Brick & Tile Co. has awarded the contract for the construction of a 1-story brick plant, to the W. F. Sparling Co., 120 Bay St., Toronto. Estimated cost, \$30,000.

TORONTO—The Sunlight Soap Co., East-ern Ave., will build a 3-story soap factory. Estimated cost, \$350,000. Work will be done by day labor.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its summer meeting at the La Salle Hotel in Chicago, Aug. 16, 17 and 18.

AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Chicago, Sept. 7 to 10 inclusive.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its Fall meeting in the Hotel Statler, Cleveland, Ohio, Sept. 30, Oct. 1 and 2.

AMERICAN FOUNDRYMEN'S ASSOCIATION will meet in Columbus, Ohio, Oct. 4 to 8 inclusive.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its one hundred and twenty-second meeting Aug. 20 to Sept. 3, at Lake Superior.

AMERICAN MINING CONGRESS will hold its next convention in Denver Nov. 15.

AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

AMERICAN STEEL TREATERS' SOCIETY, Chicago, will hold its second annual convention and exhibit, combined with the convention of the Steel Treating Research Society of Detroit, Mich., in the Coliseum Museum, Philadelphia, Pa., Sept. 14 to 18 inclusive.

FORREST PRODUCTS LABORATORY will hold its decennial celebration at Madison, Wis., July 22 and 23, 1920.

INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

INSECTICIDE AND DISINFECTANT MANUFACTURERS' ASSOCIATION will hold its midsummer meeting at Boston, July 15 and 16.

IRON AND STEEL INSTITUTE (British) will hold its autumn meeting at Cardiff by invitation of the Ironmasters and Steel Manufacturers of South Wales and Monmouthshire. The date of the meeting will be Tuesday, Sept. 21, for the assembling of the members at Cardiff, and the formal proceedings will open on the morning of Wednesday, Sept. 22.

SIXTH NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES will be held in the Grand Central Palace, New York City, Sept. 20 to 25.

TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its fall meeting at Saratoga Springs, N. Y., Sept. 1, 2 and 3.

Modern and Ancient Canada

CONSIDERABLE contrast is to be found in the Canada as seen by our colonial grandfathers and the Dominion of today which cannot be ascribed to the natural flow of the sands of time alone. The territorial rivalries between the early settlers of the St. Lawrence and Mississippi river systems and the English Colonies were productive of neighborhood rows and fights that the French priests did not want ever to be buried and forgotten. Two centuries of prayers unanswered have no doubt dampened their passion. But ancient Quebec has given way in political prestige to Montreal, Ottawa, Toronto, peoples to the west, who wish no greater heritage than their present opportunities. Railway transportation, to be sure, has made their growth possible. They did not limit themselves to the use of the bateaux or canoes, but demanded and wrought better ways of transportation.

Those who were fortunate enough to attend the Canadian meeting of the American Institute of Chemical Engineers had the pleasure of seeing modern Canada teeming with ambition. The future city of Belleville may be taken as an example. There cannot be the slightest doubt that it will forge ahead, endowed as it is with creative citizens. Shawinigan Falls has accomplished most, and credit for it should not be, of less pride to Canadians because they must share it with their neighbors the citizens of the States. For the very greatest heritages that are theirs also belong to these kinsmen of theirs to the south. The ownership of North America perhaps forms the greatest of all partnerships and the dividend of a greater language, a richer literature and a finer race of men shall be reared from North America, Inc. and Ltd. by the co-operating peoples who loyally love the Maple Leaf or American Eagle.

Strikes, Ammonia And Food Supplies

OCCASIONALLY it is possible to get such concrete evidence of the close interrelation of apparently unrelated matters that a good example is worth recording and pondering. We need an appreciation of the fact that "no man liveth to himself"; but the problem is to get the knowledge where it is most needed and will do the most good. Our present theme—strikes, ammonia and food supplies—may sound as incongruous as the classical "ships and shoes and sealing wax, and cabbages and kings," but the relation is very direct. There is an acute shortage of anhydrous ammonia in the country, and apparently it is a consequence of a series of labor strikes, first in the steel industry, then in the coal mines and finally on the railroads. The immediate effect is a crisis in some places in keeping

cold-storage food from spoiling, and extreme measures have been adopted to obtain ammonia wherever possible, even to appealing to the Government.

The steel strike last year was planned far in advance and with great care; but no one imagines for a moment that the leaders calculated the full effect of their acts. But the steel strike closed byproduct coke ovens and diminished the supply of ammonia. The coal strike, likewise, restricted the output of raw material from which our ammonia is recovered. And finally the railroad strikes have made transportation slow and uncertain and have caused embargoes to be placed on such commodities as empty cylinders, thus giving the final touch to a series of events affecting the refrigeration of perishable food. In the face of such conditions the manufacturers of anhydrous ammonia are helpless, but they know the causes of their impotence and it would be well if the whole country could have as keen an appreciation of the situation. The strikes were an offense against society and a menace to the welfare of the people, as the present example shows.

The Education Of the Chemist

THERE is vigor and forceful expression in the last report to the Society for the Promotion of Engineering Education by its Committees on Chemistry. Six important items are discussed constructively: Courses of training for undergraduate degrees; industrial and vocational courses; fifth-year residence courses; conditions in the smaller institutions; aids to training in research; and the future supply of chemists. All are timely and vital.

In discussing instruction in industrial chemistry the committee shows a lively sense of the fitness of things when it says that "much of the time so frequently spent upon the processes given in the textbooks of general industrial chemistry may be better employed in a course which emphasizes the general chemical, engineering and economic problems and their solutions, and which deals with the surmounting of the difficulties encountered in as many of the industries as time will permit. Very little attempt should be made to deal with the technical details of any process." In other words, courses in industrial chemistry should be designed to ground the student in fundamentals rather than attempt to give him a finished technique which, after all, he can never obtain from books or laboratories. School years should be devoted to the study of those things which either cannot or will not be mastered after leaving school.

The committee represents the best thought of the day when it recognizes that "the amount of time necessary to fit a man fully for entering any branch of engineering cannot be crowded into four years." One

solution is "a fifth or graduate year of directed study" which should be spent in an intensive study of methods of chemical research. It is believed that this extra year of study might well be devoted to giving the student an insight into the manner of acquiring and applying chemical knowledge, including the methods of library research. By preference this fifth year should be spent at an institution of recognized advantages, and at some school other than the student's *alma mater*, even though the latter be well equipped.

A real menace to the industrial life of the nation is seen in the increasing difficulty with which young men of ability are attracted to the teaching profession. The business world is offering such high salaries that not only are young graduates deterred from entering educational work with its meager monetary reward, but the best of the younger members of the teaching profession are deserting the schools for industrial laboratories. This means a weakened teaching staff, with consequent deterioration in the product on which further teaching as well as industry must rely. Unless something is done to remedy the situation, we face the prospect of a constantly vanishing quality as well as diminishing quantity in our teaching forces. And since "poor teachers cannot possibly train such men as are needed to enable America to take her natural place among the great industrial nations," it is obvious that more money must be found somewhere for the better compensation of teachers so that the best men can be attracted and held.

The committee makes some very pointed and timely remarks on the subject of chemical research in our colleges, but comment will be reserved for a future time.

Super-Power And Chemistry

THE super-power investigation just beginning under the direction of the U. S. Geological Survey will, we trust, be made sufficiently comprehensive to include certain industrial chemical problems. We refer to the possibility of coking coal and augmenting the supply of byproduct gas in lieu of developing electric power and building transmission lines.

In central and western Pennsylvania, northern West Virginia and western Maryland there is a source of energy. Along the eastern seaboard there is a market clamoring for a supply of energy. The problem is to transfer the resource into useful public utility and transportation supply.

The problem is three-fold. What does it cost to generate the energy in a transportable form; what does it cost to transport this energy to the point of use; and how efficiently can the energy be applied at this destination? There are three forms in which the energy may move: As a solid, coal; as a gas, made either by the byproduct or by other variations of the distillation process; or as the intangible energy, electricity. If we generate electricity we must use it instantly, for it cannot be stored at all; that is, no appreciable percentage of the supply can be stored even by the most extensive use of storage batteries. If gas is the medium, we may store it up to 24 or 48 hours supply, but usually it is impracticable to store even as much as this in large operations. On the other hand, coal can be stored for an entire season or over into a succeeding season if we have a surplus of stock. These facts are so obvious as

to have become almost trite in their significance, and yet they are the limiting factor in the swing from solid to gaseous and from gaseous to intangible energy supply.

It is, of course, for each municipality or district to determine which of the three means shall be used, but if proper thought is given to the matter the investigators of super-power possibilities will find that coking of coal and use of gas as one medium of energy transfer is a splendid supplement to the electrical possibilities which their work is certain to encourage. All of our chemical industries will be vitally affected if large-scale coke developments are thus to be considered. The nitrogen resources of the country will be augmented through ammonia production. Tar will afford additional liquid fuel, dyestuff raw materials, road-making material, roofing supplies, and numerous other commodities of large importance. The light oils which would be available from such developments would, of course, be most welcome in the field of gasoline substitutes; and they would also find numerous other applications, especially giving us very comfortable margins in toluol and xylol for military explosives in case of need. Altogether we can see a most attractive future for our industries if this subject receives that attention which we believe it fully deserves.

Technical Libraries An Asset to Industry

WE SOMETIMES wonder whether growing communities realize the value and importance of a technical library to the industrial concerns operating in their midst. Limited observation leads one to give a negative answer; for while libraries are now a common possession of even small towns, it is too often the case that the technical and scientific division suffers from neglect. The need, as we see it just now, is likely to be especially acute in the rapidly developing cities of the West. The East and Middle West are quite well supplied, at least in a few centers that are accessible to large areas; and the facility with which photostat copies and translations can be secured on short notice makes it possible for a few excellent libraries to give wide service. But the West is characterized by comparatively few large centers, separated by great distances. Scientific investigators in those cities are too remote from New York or Chicago to avail themselves quickly of the facilities offered, and they work at a consequent disadvantage.

The technical library is the first aid to industrial research. Investigation of a problem begins with a search of the literature in order to take advantage of past experience and knowledge, and this cannot be done with any degree of satisfaction unless a fairly complete library is available. Every large city in the Rocky Mountain and Pacific Coast region should have a well selected list of technical books and magazines specially suited to the industries already established there or likely to develop. San Francisco, we believe, has an advantage over some of the other cities in her Mechanics Institute library—an advantage which Los Angeles in her new pride as the largest city on the Coast should not allow to stand. Nor should the growing cities of the Northwest lag behind in this service to their technical men. It is a matter which local sections of the national scientific and engineering societies might well promote and support.

Efficient Use Of Railroad Equipment

WITH the closer interest that the public has been forced to take in railroad affairs on account of the freight moving difficulties of the past few months there has come a partial understanding of the real difficulties in the railroad situation, where previously there had been no understanding at all. Whether there had been an organized publicity campaign or not, the public had come to think that what the railroads needed was to buy more rails, cars and locomotives than available funds permitted. The public realizes now, what it could have realized earlier if the effort had been made, that the first requisite in railroading is to obtain maximum efficiency.

Cases have been cited without number of loaded freight cars being long periods in transit, nearly six months in some cases for a journey across the continent. These loaded cars were not held up by rails lacking in track or by roughness such as some highways offer to the progress of an automobile. The difficulties have been slow handling of the cars, particularly in classification yards and at junction points. If there were more cars, the congestion would simply be greater. If more men were engaged in laying rails the extra men would be withdrawn from work that might expedite the movement of freight.

While many things are needed for the future, at the present time the chief desideratum is greater efficiency in the utilization of existing physical equipment. It is a matter of men, the number of men and their efficiency. The railroads need more men, and they need more intelligent and efficient work on the part of all the men in employ, from the lowest group to the highest. The percentages in each group of men who are not doing their best work are not known, but it is a not uncommon view among those who have had excellent opportunities to observe that inefficiency does not stop at any group, but extends clear up to the highest circles.

It would be absurd to assume that in railroading men are not actuated more or less by self interest. It is the case with all other forms of human endeavor and there is no reason to suppose that railroading is totally different in this respect. Accordingly there are three events, set for the next sixty days, that promise very considerable measures of relief from the present inefficiency. The dates for these three events are: (1) July 20, when the Railroad Labor Board is expected to make its award, setting railroad wages on a competitive basis with those paid in the industries, and putting the men in a good humor, particularly on account of the increases awarded being retroactive to May 1; (2) August 1, when the Interstate Commerce Commission is expected to announce its decision in the freight rate cases whereby, whether the railroad managements are satisfied or not, they will be given all they can hope to secure at this time; (3) September 1, when the Government guarantee of railway earnings will cease and the railroads will be thrown upon their own resources and will have to make their money themselves.

The real experiment will then begin to determine what freight and passenger service can be gotten out of the present physical equipment by efficient use of the facilities. It is certain that there will be a very material improvement over present conditions. It will then be possible to determine, as it is not at present,

where and in what manner the physical equipment should be improved. More terminal facilities, more second track, more automatic signaling, more cars and more locomotives are needed, but the proportions are not determined. In some cases, additional automatic signaling will be more effective than additional cars or locomotives, while in other cases the latter will be found to be the desideratum, and thus as to all details of the problem that will then be presented, but the immediate need is better employment of existing physical facilities through more efficient functioning of the human element.

Fix the Mud-Hole

A NUMBER of prosperous farmers were compelled to haul all their produce to town over a road that in most places was in fair condition but in some parts was rendered almost impassable by deep mud-holes. In order to be able to pull through these mud-holes it was necessary to use four-horse teams, although two would have been ample if these unnecessary obstacles had not existed. One day the farmers took sufficient thought to realize that what they had been doing was not only inconvenient but a source of great expense to them. So they voted an increase in their taxes sufficient to permit the road commissioners to fix the mud-holes and keep the road in repair. To their gratification, they found that not only was the expense of keeping the road in good order much less than the cost of using four horses for a two-horse job, but they were now able to use automobiles, which proved to be a great convenience and economy. So they demonstrated to themselves that one of the ways to earn money is to spend it wisely.

Much the same situation exists in industry today and it remains to be seen whether manufacturers and the general public are as intelligent as the farmers. For three years there has existed, in varying acuteness, a coal problem. Except in the brief period in the winter of 1919-20, when stocks were probably being used up and there was little demand, the mud-hole in the road of industrial progress has always been the railroads, which are unable to transport the coal that is offered. To get the coal they require, consumers bid the price up until they bring enough economic pressure to bear so they can get coal that would be freely available at the normal price if the railroads could move all the coal that the mines offer. To be specific, coal that at Hampton Roads normally costs \$5.50 per ton, of which \$2 is the freight charge, is now eagerly snapped up at \$11 a ton and buyers cannot get nearly as much as they need. Industry is using the four-horse team of doubled prices to pull it through the mud-hole of railroad disability. It is peculiarly inefficient because the premium paid by the buyer does not go to the railroads to induce them to move more coal, but to various others who take advantage of the situation to collect "all the traffic will bear."

The remedy is simple and obvious: increase the freight rate on coal. The increased earnings of the railroads will then enable them to purchase equipment and pay wages high enough to retain their men in competition with industry. An increase in freight rates sufficient to average \$1 per ton on all the coal mined would give the railroads nearly \$700,000,000 increase in annual earnings and would cost the public less than it is now paying to get coal across the morass of the railroads' inability to handle it.

Readers' Views and Comments

Copper and Magnetite in Copper Smelter Slags

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—The article, "Copper and Magnetite in Copper Smelter Slags," by Maier and Van Arsdale, *CHEM. & MET. ENGINEERING*, June 16 and June 23, is most interesting and is an excellent illustration of the valuable assistance which the metallurgist of today may obtain from skilled research investigation.

In considering this article the writer's thoughts go back to the 80's, in Colorado, when American lead-smelting practice was so largely being developed, and the metallurgist of those days was encountering difficulties which it now seems may have been due to such reactions taking place in the flowing furnace slag, and which became manifest upon the advent of the first small amounts of sulphides in the ores. These difficulties had not appeared in the smelting of wholly oxidized ores, which had previously constituted the furnace charge.

It was at a time when those who were the leaders in the metallurgical thought of the day, basing their opinion upon their earlier experience with the Nevada carbonate ores, were led to place practically their entire emphasis upon exact slag composition, even to the extent of asserting the attainment of chemical types as being the necessary requisite to obtain clean slags.

To one familiar with the method of slag analysis upon which the dictum of exact slag types was based, the methods discussed in this article offer an interesting comparison.

Even in those earlier days, however, there was a group of younger metallurgists who already had an appreciation of the fact of physical mixtures within the flowing slag, and realized that the chemical analysis should, to some extent at least, be questioned, as an indication of the form of the oxides present.

Iles, for example, in his paper written for "Mineral Resources of the United States," (See *E. & M. J.* Vol. 41, March 6, 1886, Page 169) expresses the opinion that nine-tenths of slag analyses were wrong.

In this same paper Iles refers to the magnetic properties of lead-furnace slags, stating that in December, 1879, it was discovered that the slags at the works of the old Grant Smelting Co. were all magnetic, and mentions an examination having been made of 108 samples of slag in an attempt to discover the "relation between intensity of magnetism and lead and silver losses." He states also that the slags produced in all of the prominent smelting works of the country show more or less magnetic property.

There is no suggestion, however, as to possible chemical reaction between the higher oxides of iron and the matte, such as that discussed by Maier and Van Arsdale. Iles indicates that there was in some way considered to be a relation between magnetic properties and losses. This is also shown by the proposal of Neill to subject pots containing molten slag to the action of a powerful magnetic field. (*Trans. A. I. M. E.* Vol. XXII, page 675).

A most convincing demonstration, in those earlier days, that mechanical suspension of matte was largely

accountable for values contained in slags, and that such values could be mechanically removed, was that afforded by the experiment, carried out upon an operating scale, at the Omaha & Grant smelting works, in Denver, some time in the 80's, with a Peck centrifugal machine. The assay results clearly demonstrated that slags could be effectively cleaned by mechanically throwing out the suspended sulphides, but the operating difficulties involved in maintaining the necessarily high speed of rotation of the separating thimble, while at the same time pouring molten slag through the machine proved insurmountable. Thus through mechanical failure an important metallurgical fact was very largely lost sight of, although, with some of us, it had the effect of hastening the lead-furnace fore-hearth and reverberatory re-treatment of blast-furnace slags.

Although such reaction as is referred to by Maier and Van Arsdale, with the resulting "flotation" of matte prills, was not at all suspected, it was generally accepted as a fact that magnetite ores were unsuitable for lead-furnace smelting in that the iron content of such ores was carried into the slag without performing its share in the slag formation from silica. This was one of our problems in Mexico, in localities where magnetite was accessible and other iron ores not so attainable. It was known that the magnetite was not reduced in the furnace, and that we paid for iron "units" for which we did not get fluxing equivalent which was the real cause of their rejection.

These very interesting investigations of Maier and Van Arsdale clearly show that metallurgists should give careful consideration to the conditions indicated, not only in the smelting of converter slag, but where a similar suspension is likely to occur in slags flowing through blast furnace fore-hearths when ores having such higher oxides constitute, to any considerable extent, the blast-furnace charge.

Wallingford, Conn.

Nitrogen Fixation by the Haber Method

To the Editor of *Chemical & Metallurgical Engineering*:

SIR:—With reference to the article on the Haber process by Chester H. Jones in the June 9 number of *CHEMICAL & METALLURGICAL ENGINEERING*, a statement is made that one of the disadvantages of the Haber process is the "high royalty that would be demanded if the Government were to install and operate; and the inability to come to terms with the Badische company as to the use of its patents is reported to be the sole reason for the non-adoption of the method by two large American corporations," etc. A further disadvantage is, "Patents and processes controlled in America by one corporation."

It is true that the patents are owned by one corporation—The Chemical Foundation, Inc.; but we wish to take this opportunity to state that these patents are available to any qualified chemical manufacturer in this country at such a royalty as will not prove an obstacle to successful exploitation.

THE CHEMICAL FOUNDATION, INC.,

New York City.

S. A. TUCKER, Chemist.

Report of the Twelfth Semi-Annual Meeting Held at Montreal and of the Visits to the Leading Canadian Chemical Plants in the Vicinity of Montreal, Ottawa, Belleville, Shawinigan Falls and La Tuque

THE Canadian members of the American Institute of Chemical Engineers and their compatriot friends made the visit of the society to the Dominion from June 26 to July 5 an extremely pleasant one. The meeting as started in Montreal had few omens of the success that was coming, for the hall supplied by the Hotel Windsor was acoustically possessed by the carpenters' union, which was diligently turning adjacent large rooms into little ones to enable the hotel to house the great convention throngs to which every train from the States was constantly adding new recruits. The Engineers' Institute of Canada rescued the paper program by having the society move over to its commodious clubhouse.

The reports of council, officers and committees were received. The meeting committee reported that New Orleans and Detroit had invited the society and it was tentatively decided to hold the December meeting at the former city and the June meeting at the latter.

Mr. Ross welcomed the society to the Dominion and spoke on the functions of the chemical engineer as being very old and in continuity with the work of all other engineers.

WHAT IS A CHEMICAL ENGINEER?

President DAVID WESSON spoke as follows on questions involving membership in the society:

"On occasions like this precedent seems to have decreed that your president should make some kind of an address. Personally it has been a matter of debate in my mind whether an address or a sermon was the better sedative.

"If it were proper for me to deliver a sermon, I would take for my text, 2d Corinthians, 3d chapter, the last part of the 6th verse, which reads as follows: 'Not of the letter of the law, but of the spirit, for the letter killeth, but the spirit giveth life.' The reason for choosing this text was brought to my mind when discussing the proposed amendment, which has brought more or less discussion among our members, and not having received the necessary two-thirds vote of the members, has failed to pass. I am free to admit that there seemed to have been a good reason for the amendment when it was first proposed, but after going into the matter

fully with the chairman of our membership committee, I have concluded the amendment is unnecessary.

WORK OF THE MEMBERSHIP COMMITTEE

"Those who have not served on the membership committee cannot fully realize its importance, and the great care its members take to do justice to all applicants and at the same time to see that the high standards of our membership are maintained. I have served on a jury and I have served on the membership committee, and between the two would choose the latter if I desired to obtain a thorough impartial sifting of evidence.

"No name is allowed to go on a ballot without a careful consideration by the committee of a man's qualifications and references. The greatest attention is paid to the applicant's character and ethics. Many cases come up where there is no question about the worth of a candidate and little time is lost in putting his name on the ballot. Other cases come up where the applicant obviously wants to use the Institute for selfish or advertising purposes, or is fully unqualified, and it takes no time to turn him down.

"The Institute owes its high standing to its membership committee, probably more than any other factor. It is an honor to be elected to the Institute and the membership committee tries to make it its business to see that applicants for membership will likewise add to its luster if elected.

QUALITY DESIRED RATHER THAN QUANTITY

"The Institute, as you know, was started in 1908—just twelve years ago. Our membership at present is about 400. Up to six months ago our growth was about 24 members a year. During the past six months we have added 40 or 50 members. It seems desirable that we should increase our membership to about 600, which would be nearly double what it was a year ago. We must bear in mind, however, that quality of membership is to be desired rather than quantity, and we must not lose sight of the fact that it is possible to have a society so large that it will defeat the object of sociability among its members and make delightful excursions such as we have had in the past and such as the present one impossible from mere weight of members.

It should be our object, therefore, in the future to try to secure for members those who will add to the prestige of the Institute.

LEADERS OF ALL BRANCHES OF CHEMICAL INDUSTRY

"In the selection of new members, we should be governed by the text already quoted. There has been in the past more or less adverse criticism because the membership rules were sometimes too narrowly applied. It was some such feeling which probably started the proposed amendment which has just been rejected. I think the whole trouble has arisen from a misconception of what constitutes a chemical engineer.

"The Century Dictionary of 1909 says: 'Chemical Engineer—a degree given to graduates of a technical or engineering school for special knowledge of the scientific laws and rules of practice concerned with the manufacture of chemical products.' It is evident that if many of us applied this definition to ourselves we would find we had never taken the degree, although we were admitted to the Institute without it.

"The 1900 edition does not mention chemical engineers at all but gives as a third meaning of the word 'engineer,' 'One who carries through any scheme or enterprise by skill or artful contrivance—a manager.' The chemical engineer, therefore, is in the broadest sense of the word a chemical manager, that is, one who manages enterprises requiring the knowledge and application of chemistry. In a broad sense the head executive of a successful chemical enterprise, although not a trained chemist, might be a better chemical engineer than some man in his works who though holding the degree of chemical engineer would never rise above the position of foreman or superintendent of some small department.

"Again, the editor of a chemical engineering journal, though not practicing chemical engineering, so called, in its narrow sense, at the time of his application should, if possessed of the proper education and experience, be eligible to membership. The same rule would apply to a chemist who had turned his attention to patent law and was rendering great service to applied chemistry in securing patent protection to the industries.

"In conclusion I want to say that it is believed that the Institute should have in its membership the leaders of all branches of chemical industry; we should not wait for them to apply for membership, but should go after them. We need them and they need the Institute. The old theory that we should wait for men to apply is exploded. Naturally, many of those who apply are undesirables. We have it in our power to help the Institute by selecting the right sort of applicants ourselves and inducing them to join."

VIEWS PRESENTED IN DISCUSSION

In the discussion that followed Mr. MOORE stated that the society was large enough and that increased membership would make it very difficult to obtain desirable plant visiting privileges. Dr. OLSEN stated that there was some question as to the desirable number of members and estimated that there were only about 600 qualified men. Mr. LANGMUIR spoke of the difficulties encountered in connection with the large American Chemical Society meetings. Mr. CHUTE recommended that no limitations be set and that the society carefully select its candidates. Mr. HOWARD favored taking in all the able chemical engineers so as to make the Institute representative of the profession.

Prof. A. W. SMITH reported for the committee on education and criticised the Mann report. He also gave a summary of Dr. W. J. HALE'S recommendations on means by which industry can give support to the university staff by giving financial reward for the best publications on original investigations.

SYMPOSIUM ON ELECTROLYTIC CELLS

CHARLES B. BARYON opened the program with personal reminiscences of the pioneer work done at Rumford Falls, Me., in 1894-98 by LeSueur, MacDonald and Mercer.

HUGH KELSEA MOORE then discussed the fundamentals of the diaphragm cell, confining himself especially to the factors controlling current and decomposition efficiencies.

ALBERT H. HOOKER made a notable contribution on cathode brine liquors, giving the equilibria existing between NaOH and NaCl, from which considerable guidance is obtained in getting most economical caustic production.

L. D. VORCE'S paper was then introduced, in which the space factors were especially dwelt upon, and the advantages of the cylindrical cell pointed out in this regard.

Time was not available for any generalizations on cell economics, but the three variable factors of heat of evaporation, current and space were brought out individually in an exceptionally competent manner. It is planned to publish the details of the symposium at an early date.

CHEMICAL LIME BURNING

RICHARD K. MEADE gave an interesting account of lime burning technology, describing all types of kilns and ways of heating. The latest feature presented was the use of the kiln gases in tube boilers for the production of steam. Part of this steam was used in producing water gas, which is exceptionally efficient in lime burning because the heat of both the regenerating blast and the gas is utilized. The main factors of labor, fuel and equipment costs were taken up briefly for a few cases. An account of reburning spent sludges was given at the conclusion.

RESEARCH ON EVAPORATORS

W. I. BADGER gave the initial contributions resulting from the work of the evaporator experiment station at the University of Michigan. In his first paper on the effect of temperature drop and level on heat transmission in vertical tube evaporators, it was shown that the coefficient of heat transmission was a function of several variables. It decreases with temperature drop and approaches zero for zero temperature drop. It increases with boiling point for a given temperature drop. When corrected for hydrostatic head it varies directly with temperature drop. As the liquor level is increased above the top tube sheet, the heat transmission falls off along a straight line. This change is only partially due to the effect of hydrostatic head. Changes in velocity or circulation are a very important factor.

The vapor pressures of salt solutions with varying concentrations and temperatures were given. An excellent bibliography on the subject was included also.

CORROSION OF IRON AND STEEL

W. D. RICHARDSON presented a voluminous paper entitled "Experiments on the Corrosion of Iron and

per year. F. J. Wood designed the large multiple effect units, which are continuously charged with superheated concentrated sweet liquor.

A special train was provided by the Canadian National Railway containing five Pullmans with dining and baggage cars for the three-day tour. The beautiful capital city, Ottawa, was the first point of interest. Here the local members of the Society of Chemical Industry had provided an elaborate program. Luncheon was served, after which SIR GEORGE FOSTER, acting Premier, gave an after-dinner speech, which pointed out the great fuel problem confronting Canada. A small box containing a lignite briquet was set at each plate, that the society might have a souvenir of the occasion.

A quick tour was made over to Hull through the local pulp and lumber industry. The old Eddy mill was of exceptional historical interest, as it was operating with horizontal digesters on 24-hr. shifts, just as was the practice in 1889. After the industrial excursion, the entire party was taken around Lady Grey Drive in automobiles, where they obtained fine views of the lively Ottawa River and the stately edifices which house the various governmental departments.

BELLEVILLE ACTIVITIES

The Institute special train pulled into Belleville just before midnight, but the town was not asleep. A full military band gave evidence to this effect and after a few commands from Captain Lucius E. Allen an excellent parade and street dance were staged.

In the morning cars were at hand for the tour through the picturesque roads of Hastings County. Deloro was reached at noon, luncheon was served, more speeches were heard, and the plant of the Deloro Smelting & Refining Co. was visited. Here the high cobalt ore concentrates are roasted to sublime the antimony, salted and heated to convert the silver salts to cyanide soluble forms, the residue of which is then dissolved in sulphuric acid. Fractional precipitation of pure cobaltic hydroxide, with the nickelic coming down with higher hydroxyl concentration, was obtained by the use of sodium hypochlorite. The cobalt hydroxide is heated to form the various oxides used in ceramics, or dissolved in acids to obtain various salts, or reduced to metal. A large amount of stellite is being produced at the plant for the Haynes company at Kokomo, Ind. The silver is removed by adding aluminum powder to the cyanide, filtering, and smelting. The antimony is resublimed and ground.

On the return trip to Belleville, the large talc grinding plant of S. H. Gillespie was visited. Then the plant of the Industrial Alcohol Co. at Corbyville was passed through. This company produces beverage alcohol about one-sixth of the time. The fermenting vats were open, but it is planned to remove the alcohol vapor from the CO₂ gas emission.

INSTITUTE MEDAL AWARDED

Upon returning from the hundred mile tour, the party was agreeably surprised to find a banquet awaiting them at the Quinte. Captain ALLEN made a very excellent toastmaster and Colonel R. D. PONTON proved to be as able in commanding words as men. Dr. S. P. SADTLER gave added dignity to the occasion by reciting the extraordinary accomplishments of H. K. MOORE, whom the Institute chose to honor with its medal, because he had devoted unselfishly a liberal part of his

time in writing scholarly papers of the greatest benefit to his fellow engineers.

VISIT TO SHAWINIGAN FALLS PLANT

The Canada Carbide plant gave the visitors an excellent opportunity for seeing a three-phase carbide furnace in operation. The molten reduction product of burned lime and coke was drawn off at intervals in cast iron cars, where it cooled before being carried to the crushers. A large part of the carbide was packed in metal drums for shipment.

The electrode department was passed through enroute to the acetylene products plant. Coke was pulverized and bonded with lard pitch. The 16-in. electrodes were extruded and the volatile hydrocarbons removed by heating in kilns. Space will not be taken here for giving details on the acetic-acid-from-acetylene process, which was next inspected, as it has been recently described in this journal¹.

Buffet supper was served at the Cascade Inn. The piano was tuned up and everybody sang. Dancing was soon in order and the party did not break up until the conductor called "all aboard."

LA TUQUE MILLS AND SORTING GAP

Morning found the train sidetracked in front of the Brown Co.'s sulphate pulp plant at La Tuque. Here an opportunity was given to see digesters using the Morterude system of heating liquor, the spray process for burning the concentrated black liquors so as to recover their caustic content, a Cottrell precipitator and a new counter-current perforated drum pulp washing machine, in addition to all the usual equipment that constitutes a strictly modern pulp plant. The electric precipitator was being rebuilt at the time, as a large part of the soda vapors had not been caught by the first installation due to insufficient cooling and other causes.

The sorting gap on the St. Maurice River was exceedingly interesting, for SIMMONS BROWN had the camp cook prepare a Canadian lumberjack dinner, which was followed by an entertainment. The log rolling contest might have been enjoyed more if some of the chemical engineers had joined in and no doubt they would have done so, had they known the little joke Jupiter Pluvius had in store. None of them got back dry but they all seemed to be happy and put lots of force into "Alouette, je te plumerai la tête. le bec, le nez, le dos, les pattes, le cou, etc."

SAGUENAY RIVER

The meeting closed amid the beautiful Laurentine mountains on the Saguenay river, the greatest of mountain streams. The grandeur of Cape Eternity towering almost one-third of a mile into the sky can not be described by words. It has been left to the art of photography to convey an impression of it in our heading.

Monday and Tuesday were spent sightseeing in the historical city of Quebec. The shrine of Sainte Anne de Beaupré was the most interesting of the churches, standing out from 1658 until the present as a center of intense religious activity of the old school. About 200,000 pilgrims flock to it annually owing to the supernatural curative influences with which it is believed by them to be endowed.

The Future of Oxygen Enrichment of Air in Metallurgical Operations*

Apparent Possibilities of Applying Cheap Oxygen to Various Standardized Metallurgical Operations, Permitting Closer Economy of Blast Furnace Fuel, Reducing Atmospheres in the Open-Hearth, and Low-Silicon Iron to Converters

BY F. G. COTTRELL

ALTHOUGH oxygen is the commonest of all the chemical elements, making up nearly one-half of that portion of our globe which we have yet penetrated and is found in a perfectly free, that is, chemically uncombined state in the air, simply mixed with about four times its volume of inert nitrogen and very small amounts of other gases, still it has never yet been separated and used in any concentration above that of the atmosphere on a scale at all commensurate with its importance and industrial possibilities.

Not only is it the most common of all the elements, but it enters actively into more processes absolutely vital to human life and industry and to a far greater total tonnage than any other element. We have known of it and its striking properties ever since Priestley first prepared pure oxygen in 1774 and it has ever since been a potent reagent in the hands of the chemist for the special purposes of his laboratory. Still it has taken over a hundred years to bring it forward as a general industrial tool even to the comparatively limited extent it has already reached, while many other elements vastly rarer, inherently more difficult to extract and far less important in their practical applications, have outstripped it in the race.

This situation, in fact, presents almost an unique anomaly in our technical and economic development and can only be compared to those which ushered in the industrial application of the steam engine and later that of the electric dynamo and motor.

PROBLEM REQUIRES LARGE-SCALE TECHNICAL AND SCIENTIFIC CO-OPERATION

The reason that the possibilities and importance of very large scale applications of concentrated oxygen have not heretofore been fully appreciated and developed probably lies in the very magnitude of the project and the diversity of both technical and economic elements involved, rather than in any special difficulty inherent in any one of these individually. In other words, what is most fundamentally needed is the broad comprehensive grasp of the interrelation of these parts of the problem to one another and the ability to find, bring together and hold in active effective co-operation the specialists who can successfully deliver each element of the undertaking, be it technical, administrative or financial.

Turning to the history of commercial oxygen production we find the early industry based generally upon the decomposition of potassium chlorate by heat and the chief market for the gas in the oxyhydrogen or lime light for stereopticon and spectacular purposes with a

smaller though important field for medical use. This process of manufacture held the field for practical purposes for many years. Later came the Brinn process substituting barium dioxide for the potassium chlorate and having the significant novel feature of regeneration of the residue of barium monoxide back again to barium dioxide by recombination of oxygen from the air through a change of either pressure or temperature, thus amounting on the whole to the use of barium compounds merely as a carrier to effect the fairly direct separation of oxygen from the air.

The Brinn process came very early, however, into active competition with the production of oxygen by the electrolysis of water, the growth of this latter from about 1895 being a natural consequence of the rapid general development and introduction of electric power into industry in general.

Since in the electrolytic process the determining factor of cost is the power consumption and it was relatively easy from the first to closely approximate in practice the theoretical efficiency possible by this process, the cost of oxygen soon became standardized to the cost of power on the open market and became almost as stable as that of power itself. Furthermore, electrolytic cells were relatively easy to build and operate in units of any size and there were no truly fundamental patents to affect the situation.

The last and most important innovation was the commercial development by Carl Linde, of Munich, and later by Georges Claude, of Paris, of air separation through liquefaction and distillation.

This it was that first vividly opened up to those in position to appreciate it the real vision of the ultimate possibilities for really cheap oxygen. It did not and has not to date, however, brought any significant lowering of the price of oxygen to the ultimate consumer and this is still practically determined as far as this country is concerned by the cost of production of the 25 per cent of our present supply still manufactured through the electrolytic process, plus the cost of bottling, freight on steel cylinders and overhead of the sales and administrative machinery required in such a business.

VIEW OF THE PRESENT OXYGEN INDUSTRY

Speaking in round figures, merely to give a birdseye view of the present oxygen industry in relation to what expansion and changes application to major metallurgical operations would mean, the United States' present production is about 3,000,000 cu.ft., or say, 130 tons, of oxygen per day, over 95 per cent of which is probably used in torches for cutting and welding purposes.

The one-quarter of this produced by electrolysis comes from several hundred privately owned plants, many of them quite small, and producing gas only for their

*Paper presented at the meeting of Iron and Steel Institute, New York, May 28, 1920.

owners' uses. The remaining three-fourths of the supply comes from about 50 air liquefaction plants owned and operated by the Linde Air Products Co., using the Linde process, and the Air Reduction Co., using, for the most part, the Claude process, but with still some production from the old Hildebrand process. The first of these two companies is the older and has somewhat the larger production. Practically the whole product from both companies is compressed into steel cylinders and sold to the trade.

The largest single installation for air separation ever erected was in connection with the cyanamide nitrogen fixation plant built for the Government at Muscle Shoals, Alabama, during the war. This consists of thirty of the largest size of Claude units. It was built primarily to secure nitrogen but if operated at full capacity for oxygen would be just about equal in output to this country's total production as given above, and this in turn is just about equal to $\frac{1}{2}$ of the amount of oxygen contained in the air blown to one full sized iron blast furnace making approximately 500 tons of iron per day. The United States' average daily production of iron last year was equivalent to that of about 170 such furnaces running every day in the year.

HORSEPOWER REQUIRED TO SEPARATE OXYGEN FROM WATER AND FROM AIR

Computed directly from its heat of formation water should theoretically be decomposable with a voltage of 1.48 and a current consumption of 3,032,000 amp. hr. per ton of oxygen; or in round numbers about 6,000 hp. hr., which even at 0.2. per hp. hr. would be \$12 per ton of oxygen produced. This represents the energy of chemical combination of the oxygen with the hydrogen in the formation of water and must be supplied from without in the decomposition of the latter.

In the separation of air, on the other hand, there is no chemical combination to overcome. The oxygen and nitrogen simply dilute one another in a simple mixture of the two, and theoretically require no energy expenditure for their mere separation. Due to their mutual dilution, however, their partial pressures in the mixture are only $\frac{1}{4}$ atmosphere for the oxygen, and $\frac{3}{4}$ atmosphere for the nitrogen and as when finally separated they must both have been compressed up to one atmosphere, we must do at least this much work upon them which amounts, under assumption of isothermal compression to be about 60 hp. hr. per ton of oxygen produced, or only about 1 per cent of that theoretically required by the electrolytic process for producing the same quantity of oxygen, the byproducts being in the one case $3\frac{1}{2}$ tons of nitrogen and in the other $\frac{1}{2}$ ton of hydrogen. The values above given are, of course, the purely theoretical limits based on 100 per cent efficiency for every step of the process and piece of the apparatus employed and apply equally to any "reversible" process irrespective of whether it depends upon mechanical, physical or chemical steps. Thus, whether we try to centrifuge the gases apart, or liquefy and distill them, or dissolve them in water under pressure and re-liberate them in fractionated form from solution, or even combine the oxygen with barium oxide and re-liberate it, as in the old Brinn process, the theoretical limiting power requirements are the same and all that interests us from the power standpoint in any cyclic process is the measure in practice of its divergence from reversibility. The criteria of selection among these alternative processes from the side of

power consumption must, therefore, be based upon losses of reversibility, i.e., on friction, mechanical leakage, leakage of heat, chemical inertia and losses of thermodynamic potential generally. In practice today the electrolytic process actually reaches an efficiency of from 80 to 85 per cent and probably only very small additional gains on this can be looked for without running up fixed charges proportionally.

Of all the proposed air separation processes, that of air liquefaction and distillation seems not only to have already outstripped all others in the race but to present naturally the most attractive features for large scale development.

CENTRIFUGAL SEPARATION OF OXYGEN FROM AIR

Under very high centrifugal force there is an appreciable tendency for air to stratify into layers of increasing oxygen content toward the periphery of the rotating mass, but the effect is rather small for the magnitude of centrifugal force we can expect to reach safely on a large scale with the strength of materials of construction now available. If we think of this as a continuous process with the air steadily flowing through the apparatus, very special precautions would apparently be necessary to prevent the current from disturbing the process of stratification, as there would be no sharp boundary between layers of different composition as there is between liquid and gas in the liquefaction process. There have been numerous patents taken out on the centrifugal separation of gases, but none of them as yet published seems to meet in comprehensive detail many of these fundamental difficulties, though one would be rash indeed to predict that human ingenuity may not yet produce something of practical value in this field. However oxygen and nitrogen, with a ratio of densities of only 7 to 8, present one of the most unfavorable pairs of gases which could be selected to which to apply the centrifugal method so that, if it ever is worked out in practice, it is apt to find its best competitive field elsewhere, at least at the outset, say for example, in separating hydrogen from water gas where the ratio of densities is from 50 to 100 times as favorable for this method.

Solution of air in water and re-liberation by drop in pressure also effects a concentration of the oxygen, as it is more soluble than the nitrogen. If high concentrations are desired, it becomes necessary as in the case of centrifugal treatment, to repeat the process several times. The process, while simple, would require, however, either very large equipment, or the use of very high pressure, or both, when compared to direct liquefaction.

The use of a chemical absorbent like the barium oxide of the Brinn process, would be much more practical and attractive if we could find some cheap and stable substance which had much the same properties as the hæmoglobin of the blood with respect to the absorbing and liberating of oxygen without waste of energy. Up to date, however, none of the many substances which have been suggested for the purpose have proved to combine these desirable qualities in sufficiently high degree to promise serious competition with the liquefaction process.

EXPECTED ECONOMIES IN FRACTIONAL SEPARATION

The power efficiency in commercial air separation plants already reached on the other hand has probably not much exceeded if indeed it has reached 10 per cent

of the theoretical as above given. Here, however, there is a much more hopeful outlook for improvement, as there seems no fundamental reason why we should not multiply the present efficiency several fold by applying the same sort of good intelligent engineering which has brought the steam engine to where it stands today, as the elements of the problems are fundamentally almost identical.

Even with present equipment, the power cost item in air separation is of an order of magnitude comparable with the items of fixed charges, labor and other costs, in all of which further reduction can also reasonably be expected.

In considering items of cost, and especially as concerns installation and power, it is well to bear in mind that if the oxygen plant is included as an integral part when the metallurgical works are first built, a very considerable saving may probably be made through the reduction in size or the entire elimination of other structures, such as stoves, dust catchers, gas mains and the like and that a number of power savings might likewise probably be effected, though the detailed discussion of this belongs more properly under the later head of the metallurgical applications themselves. The development of this work is strictly an engineering project dealing with the handling of large masses of material and must be approached through practice at every point as contrasted with laboratory and experimental methods.

The possible effects to be expected from oxygen enrichment of the air stream must be rather carefully distinguished under several different heads.

EFFECT OF OXYGEN ON CALORIFIC INTENSITY

The effect which we are most apt to think of first is simply raising the temperature. This may be beneficial and important in some cases, but most of our present metallurgical processes are already standardized to pretty definite temperatures for very good reasons and, if enrichment of air is applied to them, the chief reasons will probably be other than for a temperature change per se. In fact, many temperatures in metallurgical operations are more definitely defined by the character of the charge than is always recognized even by those most familiar with practical operation. This is particularly so in blast furnace operations for, if more heat units are supplied or less taken away the furnace simply runs faster, but the temperature of the metal, and slag, can vary only slightly, as these are nearly though not quite completely determined by the composition and consequent melting point of the charge. The temperature of the coke and gas current in the furnace, especially in its lower position, may, of course, rise very considerably and this in turn slightly superheat the metal and slag as they fall through the lower part of the furnace filled chiefly with coke.

The most important way in which enrichment of blast may essentially influence blast furnace temperatures is indirectly by allowing variations in composition of charge, e.g., making of ferrosilicon or ferrochrome directly in the blast furnace. In the case of the open-hearth, and especially the converter, the temperature question is a more pertinent one, as their operation is not controlled by the melting and automatically flowing away of their charges.

On the other hand, the distribution of heat between the hearth and shaft of the blast furnace is tremendously influenced by enrichment of the blast with oxy-

gen because of the diminution of the total amount of gases going up the shaft per unit of carbon burned. It must be remembered that the blast furnace is of all our metallurgical equipment the most complicated from the standpoint of interrelated mechanical and chemical processes going on inside of it and has reached its present state of development by very gradual and conservative steps over a long period. It may therefore not present the most favorable unit on which to commence the regular use of enriched air for standard and continuous operations.

In fact if we ever come to use highly enriched air in making ordinary pig iron the resulting furnace is apt to have very little resemblance to the blast furnace of today. Our experience in the meantime with electric furnaces should help greatly in this evolution, as the conditions to be fulfilled in an enriched air furnace may reasonably be expected to lie between those of the electric and the present blast furnace.

ATTRACTIVE USE AS STANDBY

As the blast furnace, however, is the piece of equipment requiring the most continuous and uninterrupted operation, it may be that the enrichment of air for it as an emergency measure in case of trouble such as a threatened freeze-up may prove of considerable importance. Not that freeze-ups really happen with the frequency which one would assume from their prominence in text books and discussions, but that this very infrequency may mean that blast furnace operators have come to work with so safe a margin of conditions to avoid them, that this insurance is costing daily in coke consumption and other requirements or results very much more than we realize, and if one could have a standby source of oxygen for enrichment purposes in case of emergency, even though it were not used at all in normal operations, it might permit of safely running on a very much closer margin in the heat allowance of the furnace and making important improvements in its general economy and efficiency.

Another important effect of the enrichment of the air would be the higher calorific value of the blast furnace gas obtained as a byproduct due to elimination of part of its nitrogen. This in turn should mean cheapening of gas engine and other equipment on which it may be used. Furthermore the removal of nitrogen from the blast air would tend to eliminate the necessity for hot blast stoves which at present consume about $\frac{1}{4}$ of the total heat value of the gas produced in the furnace.

OXYGEN IN OPEN-HEARTH

The open-hearth presents some of the most interesting possibilities for the application of oxygen, particularly in those operations where the electric furnace has been the open-hearth's strongest competitor, e.g., where very high temperatures coupled with a reducing atmosphere are desired, as in the elimination of sulphur as calcium sulphide. With an open-hearth using ordinary air in order to reach the highest temperatures now attainable, a complete and carefully balanced combustion of the gases must be secured resulting in a neutral or slightly oxidizing atmosphere, whereas if part at least of the furnace's burden of inert nitrogen could be removed by the use of enriched air the same temperature could be reached while still leaving a residue of unburnt material in the gas, thus producing a strongly reducing atmosphere. By enriching the air the total

volume of gases passing through the furnace per unit of fuel burned and heat produced may be cut down enormously, since in the air there are four volumes of inert nitrogen to every volume of useful oxygen. This would greatly facilitate heat exchange and reduce mechanical difficulties such as dust losses, maintenance and control of draft and the like, or on the other hand permit of speeding up the furnace and thus increasing its daily output and correspondingly reduce fixed charges and labor per unit of product.

If we carry the application of oxygen back of the open-hearth to the gas producer we may still further extend the same principles and deliver to the furnace more thermal units per unit of primary fuel consumed; beside the actual saving of fuel which this represents, it may in some instances be still more important in cutting down the amount of impurities, especially sulphur, carried into the metal from the fuel. Aside from both of these considerations and viewing the gas producer simply as an isolated unit in connection with either heating or power operations, oxygen enrichment of its air supply will permit the use of fuels which could not otherwise be burned in it at all and thus vastly increase our available fuel resources.

CONVERTING PRACTICE

In the matter of possible application to the converter it is perhaps hazardous to speculate in advance of actual experimentation, but once an adequate supply of oxygen is available in the steel works such experimentation will almost inevitably produce useful results, some perhaps from directions we least expect. One of the conditions limiting what metal may go to the converter is the fuel value of the metalloids it contains and in many cases we are paying rather heavily through operating conditions of the blast furnace to put silicon into iron largely for its fuel value later in the converter. A good part of these heat requirements might be removed by abstracting part of the dead load of inert nitrogen from the converting air. Whether such a procedure might lead to a change in our practical classification of bessemer ores is an interesting question, but there seems to be so much difference of opinion at present and so many factors enter into the problem that all that can here be done is to merely mention the problem as suggestive of the wide and intensely interesting field of possibilities which cheap oxygen will open up.

In the copper blast furnace running on sulphides with its relatively short shaft and hot top, the advantage of oxygen enrichment is much less open to question than in the case of the iron furnace. Furthermore in all furnace treatments of sulphide ores the problem of disposal of the sulphur in the waste gases is one of ever increasing acuteness as our mining and smelting communities with increase in surrounding settlements meet with more and more exacting conditions with regard to fume and smoke abatement. One of the difficulties in the way of the successful economic treatment of many of these gases for the removal and utilization of the objectionable constituents has been the great dilution of the latter and consequent large volume of inert gases to be handled, a situation which may have quite a bearing on the interest manifested in the problem under discussion. In this connection the use of oxygen may also prove the key to the commercial recovery of sulphur in elementary form from sulphide ores which has been a very elusive and at times a very live problem ever since John Holway's classic work on pyritic smelting in 1878. Also in the roasting of difficultly burning

sulphide ores such as those of zinc and very low grade copper ores and tailings preparatory to leaching, the availability of cheap oxygen will be very important especially where the resulting gases are to be further utilized for their sulphur dioxide content either for sulphuric acid manufacture or for other purposes.

Last but perhaps not least may also be mentioned the part that oxygen may play in some of the newest developments of general metallurgy, viz., volatilization processes, where in contrast to most of the older metallurgical processes high temperatures may in themselves play an important rôle. Aside from zinc, cadmium, and mercury it is only lately that we have seriously concerned ourselves with the primary recovery of metals by volatilizing them from their ores but just as hydrometallurgy after a long and discouraging struggle finally won a foothold through the successful application of the cyanide process to gold and silver ores, so now what we might term "gas-metallurgy" seems also struggling for recognition and finding encouraging applications to lead, copper, gold, and silver, to say nothing of potash and phosphorus.

But these last two carry us off again and still further into the field of applied chemistry, where besides the very important group of carbides and nitrides there are a host of other applications for cheap industrial oxygen, even the mention of which the limitations of time and the intended scope of this paper forbid.

Light Creosote Oils in Wood Preservation*

Service records have shown that light creosote oils properly injected into wood will prevent decay until the wood wears out or checks so badly that the untreated portions are exposed.

Creosotes used in ties from twenty-five to fifty years ago were for the most part oils having 50 per cent or more distilling below 235 deg. C., with a residue not to exceed 25 per cent at 315 deg. C. The ties so treated lasted fifteen to twenty years, and failure was traceable in most cases to mechanical wear, such as rail cutting and spike killing. In no case was failure found to be the fault of preservative.

Of 1,558 telegraph poles in the Montgomery-New Orleans line, which were pressure-treated with a light creosote oil, 1,049 poles were still sound after sixteen years. In 91 per cent of the cases of decay, the fungi had entered the wood through checks and shakes. Representative sections in the Norfolk-Washington line showed that after seventeen years' service, of the 1,614 poles inspected, 1,469 were sound, 92 decayed at the top, and 105 decayed at the ground line. The decay at the top was caused chiefly by cutting off the poles. In those decayed at the ground line, the causes of failure, as determined in 88 per cent of the cases, were checks or shakes. Here again, as in the ties, the preservative outlasted the mechanical life of the wood.

Unless some other factor than protection from decay is considered important, therefore, there is apparently no need to specify high-boiling oils. The important point is that any coal-tar creosote which is not extremely low boiling or extremely high boiling will satisfactorily prevent decay, and in the selection of an oil, factors such as price, penetrability and convenience in handling should receive greater consideration than moderate differences in volatility.

*From Forest Products Laboratory Technical Notes, June, 1920.

Czechoslovak Glass Situation

NOTWITHSTANDING constantly increasing production, Czechoslovak glass factories are oversold for some time to come. There are dealers who have accumulated fairly good stock from whom goods can be secured, but as a rule manufacturers cannot accept orders for early delivery. New concerns have been organized with large modern plants. Four establishments have been completed and the latest machinery is being installed. These, with sixty additional enterprises are expected to increase the normal pre-war capacity by 50 per cent. The present production in the Czechoslovak glass industry, according to Engineer Josef Soukup, secretary of the Czechoslovak Glass Syndicate, can be estimated from the quantities of coal needed in the industry and the number of tons actually allotted to it. In the month of March, 1920, the entire coal demand of the glass industry was 155,418 metric tons and the allotment was 83,445 tons. April, 1920, the demand was for 160,125 tons, and the allotment was 71,138 tons.

The following is a list of what is known as the hollow and cast glass section, which is said to operate at 60 per cent of its capacity:

- Sixty-six ordinary hollow-glass factories.
- Nineteen cast-glass factories.
- Eleven machine cast-glass factories.
- Fifty-two cut-glass factories.
- Twenty-four factories manufacturing lighting fixtures, globes, shades, etc.
- Eleven factories manufacturing glass rods and tubes.
- Nineteen factories making crude glass for the Bor (Haida) fancy glass.
- Seventeen colored composition and special glass factories.
- Three watch-crystal glass factories.
- Three chemical glass factories.

Before the war these products in the former Austro-Hungarian Empire were valued at 137,400,000 crowns (the normal value of the crown was \$0.203 U. S. currency) whereof the share of factories located in the present territory of Czechoslovakia was 120,500,000 crowns. The present monthly production amounts to 25,000 metric tons, with prospects of its reaching in the near future 35,000 tons a month. Eighty per cent thereof, comprising principally glassware for household use, cut glass, chandeliers, lamp chimneys, bulbs for incandescent lamps, watch crystals, and chemical glass, has been exported.

WINDOW, MIRROR AND PHOTOGRAPHIC GLASS

The window-glass industry, which comprises twenty-nine factories, twenty-four of which are manufacturing window glass, three blown-mirror glass, and two photographic glass, are operating at 75 per cent of their capacity. A 25 per cent increase in production is in view on account of the intense demand and improvement in conditions generally. Eighty-five per cent of the output is exported, since 15 per cent of the output is sufficient for domestic needs. Photographic glass is manufactured almost entirely for foreign countries. Before the war the total Austro-Hungarian production of window glass was 12,060,000 sq.m., of which 10,900,000 sq.m. was manufactured in the present territory of Czechoslovakia. Fourcault machines are mostly used. Some concerns use window-glass machines under a license from an American firm, which machines are found very satisfactory.

During the war the inability to secure copping wire from America made their operation difficult because a

substitute that was tried gave poor results. Six factories which manufacture cast smooth and ribbed glass for buildings and four factories making cast mirror glass are operating at 60 per cent of their capacity. Fifty per cent of the product is exported as mirror looking glass, and 30 per cent is exported partly manufactured, leaving 20 per cent for domestic needs.

OUTPUT OF BOTTLES

Plants making all varieties of bottles, seventeen in number, are operating at 35 per cent of their capacity. During the year 1919 they were in a position to turn out 171,000,000 bottles. Since their output was limited by the quantity of coal, soda, potash, and other raw materials needed in their production, the actual production was only about 60,000,000 pieces. In pre-war time, in the territory of what is now known as Czechoslovakia, 165,000,000 bottles were manufactured annually, while in the rest of the Austro-Hungarian Empire only 15,000,000. In Czechoslovakia 49,500,000 bottles were consumed, leaving 115,500,000 for export. The factories have recently installed several American machines, so that their productive capacity has been increased to 240,000,000 pieces.

FACTORIES USING COAL AND WOOD

In all there are 156 glass factories in Czechoslovakia. The oldest are located near forests because of the wood that was needed in glass production. But with the increase in the price of wood and owing to the discovery of factory production with the use of chemicals, soda, potash, and glauber salt, the factories have been gradually giving way to those using coal exclusively of which there are now 103; fifteen factories still use wood only, and twenty-one use both wood and coal. Five of the old plants have been abandoned and four are not in operation.

The seventeen special and colored composition glass factories are small concerns.

OTHER GLASS ENTERPRISES

In addition to the regular glass plants there are over 3,500 independent enterprises that finish partly manufactured glass products. Besides these there are thousands of homes where practically all the members of the family do work which cannot be done by machines. This is mostly in the Gablonz industry, which employs in all about 50,000 people. Until recently the Gablonz goods exports amounted to a value of about 90,000,000 Czechoslovak crowns a month. The climax was reached about the middle of April of this year, when the effect of the rising value of the crown was noticeable. Since then exports have fallen off about one-third. The increase by the Government of the export tax on Gablonz goods from $\frac{1}{2}$ per cent to 5 per cent of the invoice price has had a deterrent effect.

While soda and potash are manufactured in Czechoslovakia, great quantities must be imported from Austria and Germany. About 1,000 metric tons of potash, it is said, would cover the needs of the glass industry for one year, and domestic production thereafter would be sufficient; fifty tons of saltpeter, 1,000 tons of glauber salt, twenty tons of boric acid, 100 kilos of selenium, and 20 kilos of gold must be imported monthly for the industry; 2,000 kilos of nickel and about the same quantity of cobalt are the annual requirements.

Chicago Section Meeting, A. C. S.

THE June meeting of the Chicago Section of the American Chemical Society was held on Friday, June 25, at the City Club.

Dr. L. V. Redman, in retiring from the chair spoke of the appreciation he felt toward the members of the society for the support they had given him during his regime. When he came into the chair he thought that the control of the section was sort of a closed ring or corporation, but found after two years' service that it was hard to get anyone into the ring, and that the corporation had to sell its stock on a poor market. He assured the new chairman, Dr. W. Lee Lewis, of the continued support, that he may be happy when he lays down the gavel of office.

Dr. Lewis, in taking the chair, said that by many political maneuvers he had now acquired the chairmanship, and that the Chicago Section must make the best of it. The chief concern of the section now is over the sixtieth convention of the American Chemical Society. The event places the Chicago Section as host in a most delicate position where vigor without violence is required. The mechanical work of the convention is progressing and the spiritual part is in the hands of the members of the section. While this convention is for the purpose of presenting papers, man is not essentially an intellectual animal, and the social side is therefore important. It is up to the Chicago Section to convince our visitors that we are democratic, friendly and genial. "This lies in the hands of the members."

The Section committees for the coming year are as follows: Program committee, J. A. Hynes, chairman, David Klein, Frank DeBeers and Paul N. Leech; finance committee, Herbert N. McCoy, chairman, Robert J. Quinn and W. R. Smith.

Dr. Lewis spoke further of the splendid work done by the retiring chairman and group of quiet unselfish members back of this section. A rising vote of thanks was made to Dr. Redman for his service.

The paper of the evening was presented by Roy C. Coleman of the Essenkay Products Co., as follows:

COLLOID CHEMISTRY IN INDUSTRY

There are certain well-founded criticisms against colloid chemistry to the effect that the colloid chemist generalizes too much. There is a divergence of opinion as to what colloid chemistry is and a review of the literature discloses the reason people think of it as a theoretical science. It is necessary to get away from usual theories to understand certain phenomena explained only by the colloidal theory.

In considering colloids, we first have a physical state of matter, and second, we have to do with the chemistry of material in that physical state. It is a state, not a kind, and an effect, not a cause.

We must not generalize, but define. Every phenomenon is not explained from a standpoint of colloid chemistry. What is the colloidal state? It is physically heterogeneous. Ostwald says: "It is the chemistry of neglected dimensions." Another writer calls it "dispersion chemistry" and another "the mathematics of chemistry." It is necessary, then, to have dispersion of one matter in another.

There are limits as to the size of the particles. The lower limits consist of mechanical mixtures with particles say 1μ in diameter. The higher limits are mole-

cular dispersions with the particles 0.1μ in diameter. The great field between these two limits contains particles said to be in colloidal state.

EMULSOIDS AND SUSPENSIDS

It is a state of matter, then, where one material is dispersed in another and this substance has the property of greater subdivision the nearer it approaches the mechanical solid and vice versa. It also possesses the property of great total surface of particles. We are not concerned as to why these matters disperse one within the other, but with the fact that they do disperse. If the particles are large they are called suspensoids and if smaller or approaching the upper limits they are called emulsoids. Emulsions may be either emulsoids or suspensoids.

"DISPERSION IN NON-AQUEOUS SOLUTIONS

The literature deals largely with the dispersion of solids in aqueous liquids. The experience of the writer has been along lines of dispersions of solids or pigments in non-aqueous solutions like oils. We use certain things in the art because they have a definite physical state which is very often of greater importance than their chemical composition. Oils and varnishes, therefore, offer an excellent opportunity for the study of colloids.

Take for example oxidized linseed oil which is made a solid by heating or blowing air through the solution, or if it does not become solid it is at least very viscous. As these solids form, particle-surface increases. In suspensoids there is not much change in the viscosity of the solution but emulsoids will increase materially toward the solid state. There are many phases in these mixtures which depend upon the material and the dispersion medium.

This dispersion occurs without chemical action due to certain degrees of surface tension. The degree of dispersion depends on certain surface energy which causes the breaking up of the particles. This is particularly proven by placing pigments in oil. Certain liquids such as oils are of colloidal nature in themselves, and therefore tend to disperse the added solids more easily. Some of these colloidal liquids are in themselves of high viscosity.

DISTINGUISHING COLLOIDAL AND MOLECULAR SOLUTIONS

The application is found in the manufacture of oil cloth, where the solution is built up to a certain amount to get the rigid or solid material. The colloidal solution may be distinguished from molecular solutions by an observation of the action during this building up where viscosity is plotted against temperature. Molecular solutions show a straight line while colloidal solutions show a curve. There may even be a definite break in the curve where change occurs from the molecular to the colloidal state.

Solids may be dissolved in solids to get either colloidal or molecular solutions. Resins, gums, etc., are colloids themselves, and when mixed, may become either molecular or colloidal solutions in the fluid dispersion mediums. There are three different ways this works out with solids. Where the colloidal solid is soluble in the dispersion medium, molecular solution is formed, as when gums are dissolved in benzol or analogous compounds. If the solid disperses in the medium without breaking up we have the second state. Many gums do

this as a class in turpentine for dispersion medium, as the solid colloid is added.

The third class is where adsorption takes place to a certain limit, at which point the solid separates out from the solution. Shellac in alcohol is an illustration. If 6 lb. of shellac is dissolved in 1 gal. of alcohol, a viscous stable solution is formed. If more alcohol is added, for instance with a ratio of 5 lb. of shellac to 1 gal. of alcohol, a slight separation takes place and this will continue as more is added until all the shellac would separate out. Certain polymerides and varnishes act in a similar manner. This third condition, then, is a form of adsorption in which the solid is dissolving the liquid instead of the reverse. In practice this applies to many varnishes and protective coatings, and is of great importance in paint mixing.

PAINTS AND ENAMELS

Colloidal oils may cause a very fine dispersion with zinc oxide, barytes, magnesium silicate, etc. Where a high colloidal viscosity is reached, a range of dispersion may be secured with zinc oxide in oil from 15 to 95 per cent, depending on the oil used. In the manufacture of body paints and fine enamels the dispersion must be very fine to secure proper smoothness on application.

In experiments with china clay, whiting, barytes, and silica as a class with a medium viscous oil, china clay was found to give a plastic paste, while with silica a viscous paste and liquid like molasses were obtained. This is caused entirely by a different degree of dispersion of materials. Solutions in rubber operate in the same manner as with oil. Hardness and elasticity are determined by the amount of dispersion.

We can, therefore, by a study of the viscosity, of liquids and dispersion, find many things of practical importance. The practical laboratory tests for determining the colloidal condition or extent of viscosity due to colloidal condition may be determined by testing with adsorption of a certain strength of caustic soda. The word "absorption" is very much abused in this connection. Absorption is applied to any kind of taking up of material or liquid, as in the case of water in a sponge, while adsorption is a form of absorption like the taking up on the surface of the particles, as in a gel.

Chemists Studying Uses of Wool Waste

The Bureau of Chemistry, United States Department of Agriculture, has been carrying on experiments to determine profitable uses for the grease and other substances found in the scouring of wool.

Chemical analysis of a large number of samples of all grades and kinds of unscoured wool show that the percentage of grease varies widely even in the same grade or class, but is high in nearly all grades. In Ohio delaine, a very greasy wool, the grease varies from 17.8 per cent to 41.9 per cent. This means that in every hundred pounds of unscoured wool containing the highest percentage there is more than 41 lb. of grease. The profitable utilization of such an item is well worth the serious attention of the wool-scouring industry.

Tests of the suitability and adaptability of the grease to various uses, including leather dressing, waterproofing and manufacture of varnish and lanolin, are being made. There is a constant demand for lanolin for use in the manufacture of cosmetics and ointments. Methods for the economical recovery of potash, soapgrease and fertilizer are also being developed.

What Can Be Done With It?

A corporation recently organized to take over one of the large government powder plants for the purpose of selling the buildings and land in sections to new industries has found itself with several buildings of peculiar styles and construction apparently unsuited for peace time industrial purposes. Most of them, however, have been converted and utilized, with the exception of the building pictured herewith. The engineering and sales departments have racked their brains for an idea of what use this building can be adapted to, or what industry could utilize it, but without result. It seems ideally built for a concentrating plant but the fact that no minerals except soft coal are to be found

within several hundred miles does not make this seem feasible. A shot manufacturer might be interested were this field not already overfull. The owners have appealed for an idea and the problem is presented to our readers. Suggestions may be addressed to the editor.

There are five of these buildings in a row. The construction is frame with an elevator occupying the square offset. The dimensions are 40 x 40 x 80 ft. high to top of roof truss; to extreme top is 112 ft. The chute down in the foreground was to be used by the workmen as a fire escape, the building being used for blending gun powder. The interior is of tin construction.

Say "Flammable," Not "Inflammable"

The National Safety Council, the National Fire Protection Association and similar organizations have set out to discourage the use of the word "inflammable" and to encourage use of the word "flammable" instead. The reason for this change is that the meaning of "inflammable" has so often been misinterpreted. Some persons have thought of the first two letters of this word as the prefix "in," meaning "not," or "non," as in "inactive" (not active) or "incontrollable" (not controllable). "Flammable" is shorter, more definite and cannot be misunderstood. The negative of "flammable" is "non-flammable."

BY WELLINGTON GUSTIN

Correspondence and Telegrams Held to Constitute a Valid Contract

How a mass of correspondence, telegrams and such may, together, constitute an agreement or contract is shown in the suit of the National Smelting Corporation against Cutler Bros. and the Superior Metal Co. Action was brought to recover damages for breach of an alleged contract to sell and deliver to the smelting company, within a reasonable time, 25 long tons of Chinese No. 1 tin, minimum 99 per cent pure, at 82c. per pound c.i.f. Pacific Coast. It appears that prior to the time of delivery defendants gave notice that they would not fulfill their agreement, but would repudiate it, whereupon plaintiff was obliged to buy the tin in the open market and pay 91c. per pound. The case was discontinued as to the Superior Metal Co. upon the showing that it was only a broker in the transaction.

There were various letters and telegrams passed between the parties, beginning with the telegraphic offer of the Superior Metal Co., of New York, to Emar Goldberg, at San Francisco, on April 6, 1918, advising him that a firm bid would probably secure "25 Chinese" on steamship Canada, reported to have sailed on March 26 from the Far East, at 82c. per pound on the Pacific Coast. Goldberg replied that his party thought the price was high, but would accept confirmation at 82, and asked the broker to try to secure a price of 81 and wire confirmation to National Smelting Co., San Francisco, which he said was "O.K." On April 8 the broker telegraphed the National Smelting Co., confirming the purchase for it of "25 Chinese tin," as per telegram of April 6, at 82c., sellers Cutler Bros., and said, as its name was unknown in New York, it was requested to telegraph references. The smelting company did this, referring to the First National Bank in San Francisco. This was further confirmed by letter dated April 8. Now, on the same day, the broker (Superior Metal Co.) telegraphed the smelting company, asking it to have the bank telegraph a guarantee of payment on presentation of documents on arrival of the tin at the Pacific Coast, as it had no rating, and Cutler Bros. were becoming impatient, as they could sell the tin in New York at 86c.

MORE LETTERS AND TELEGRAMS

In the meantime the smelting company had written the broker confirming its telegram, giving its bank references and further confirming its purchase of the tin. On April 9, it sent the broker a telegram saying it was prepared to take care of the draft on arrival of the tin. Goldberg also telegraphed the broker that Cutler Bros. would be held to the contract if the tin was not delivered. The broker prepared contracts and sent them for acceptance of the smelting company. These were accepted and returned, but were never signed by Cutler Bros. On April 12, Cutler Bros. wired the First National Bank of San Francisco, asking if it would guarantee to pay their draft for twenty-five tons of Chinese tin sold National Smelting Co. On the same day Cutler Bros. wrote the broker, quoting this telegram, saying that unless they received answer from the bank

that day, they would not sign the contract prepared by it, but would return such contract and consider same cancelled. The bank replied on April 13, accepting the order for payment of the draft, saying guaranty was unnecessary.

On April 17, the bank sent a telegram to Cutler Bros., advising them that the bank had opened a credit in their favor for \$50,000 for the account of the smelting company to cover drafts as shown by the bills of lading attached, calling for the tin. On April 18, Cutler Bros. wired the bank that they would not accept the guaranty at that time. In the meantime, the smelting company had telegraphed the broker (on April 16) that the bank guarantee was no part of the contract, but, to avoid trouble, it had gotten guarantee.

VALID CONTRACT ESTABLISHED, SAYS COURT

The series of telegrams and letters was held by the trial court not to constitute a contract valid and existing between the parties, but the Supreme Court of New York, Appellate Division, thought otherwise, and reversed judgment of the lower court. It said all the necessary elements of a valid contract appear to have been understood to be present by the parties, and nothing was left to any future agreement. Cutler Bros. did not claim that the written contract, drawn up by the broker metal company, did not contain all the elements of a contract as agreed upon by the parties in conformity with the telegrams, and the refusal to carry out the contract by Cutler Bros. was due solely to the failure to furnish them with a bank guarantee, said the court.

When a valid and binding contract had been made between the parties, neither had the right to impose other conditions. The additional condition for a guarantee (and not a reference) was made by the sellers, Cutler Bros., apparently in the hope, says the court, that it might furnish a pretext to break the contract, as they desired to obtain a higher price for the tin on a rising market. They insisted on an immediate reply and claimed same came too late, though the buyer was under no obligation to do anything further, but yielded in its desire to receive the tin it had bought in good faith.

Delivery Delay Excused by Mandatory Order from Government Where Contract So Stipulates

The Supreme Court of New York, in Appellate Term, has ruled, on a case appealed to it, that the seller, having taken an order "subject to war hazards and to delays due to Government action over which the seller has no control," was not required to make delivery of the products within the time specified in the contract of purchase, where he was unable to do so because of a mandatory order from the Government for a large portion of his June product. (180 N. Y. S., 447.)

Where the seller brought an action to recover for buyer's refusal to accept goods, and the buyers defended on the ground that the goods were not delivered within the time specified in the contract, it was a question of fact, to be determined from evidence, whether the buyers had by their conduct led the seller to believe that delivery within the contract time had been waived.

Again, where the buyer's conduct had led the seller to believe that delivery within contract period was waived, the seller would be entitled to a reasonable time notice of a new delivery date before being held in default.

Properties and Constitution of Glues and Gelatines—II

The Effect of Electrolytes Upon Degree of Dispersion; and the Structure of Gelatine Sols—Action on Viscosity Not Regular—Protein Ions—Thread-like Structure—The Relation of Melting Point to Viscosity of Jell Strength*

BY ROBERT H. BOGUE, PH.D.

THERE is considerable evidence tending to indicate that viscosity is very greatly influenced by degree of dispersion, and many facts even suggest that many of the previously described factors¹ affecting viscosity do so through the medium of producing a change in the degree of dispersion.

The relation between viscosity and degree of dispersion does not, however, appear to be a simple one. Throughout the literature on the subject one finds the citations about equally divided between those who obtain a decrease in viscosity with a decrease in degree of dispersion, and those who find the ratio to vary inversely. Wo. Ostwald² arrives at the conclusion that "other conditions being constant, a dispersoid reaches its highest viscosity at a medium degree of dispersion," but adds that "the experimental verification of such a conclusion is a problem of the future." Results obtained in the present investigation not only confirm this point of view but perhaps may furnish a part of the "experimental verification" desired by Ostwald.

The structure of solutions of the proteins has long been a ripe subject for speculation, and some of the work described herein has led to the presentation of a modification of the net-structure theory.

THE EFFECT OF ELECTROLYTES UPON THE DEGREE OF DISPERSION

In testing the effect of several electrolytes on jell strength, it was found³ that in nearly every instance the presence of the electrolytes decreased the jell strength, there being in some cases a preliminary slight increase. There may conceivably be three ultimate reasons for such a depression:

The degree of dispersion may be increased. It is reasonable to assume that a molecularly dispersed system would be of more nearly a watery consistency and would not jell.

The degree of dispersion may be decreased. We have direct proof that the jell strength is considerably lowered and may even remain liquid, when the degree of dispersion is so far decreased as to result in visible flocculation.

The protein molecules may have undergone hydrolysis. This point was tested by precipitating the protein of a glue, after it had been in contact with different salts for some time, in a 35 per cent saturated solution of magnesium sulphate. The per cent of nitrogen thrown down in the precipitate was in each case greater than that of the control to which no salt was added, as is shown in Table XX.

In the light of the information obtained from a large number of experiments on the magnesium sulphate pre-

cipitation of the proteins of glue,⁴ it becomes permissible to conclude that the added salts do not produce any cision or hydrolysis of the ultimate protein molecules themselves. We conclude, therefore, that the lowering of the jell strength may be due either to an increase or a decrease in the degree of dispersion.

ACTION ON VISCOSITY NOT REGULAR

The effect of the added substances on viscosity⁵ is not so regular as the effect on jell strength. We find these substances arrange themselves into four groups with respect to their action on viscosity

Those which raise the viscosity constantly.

Those which lower the viscosity constantly.

Those which raise the viscosity to a maximum, beyond which they produce a drop.

Those which have no appreciable effect.

In studying the causes of this irregularity of action, we are especially aided by the third class, which produce first a rise followed by a decrease in viscosity. Sodium hydrate and acetic acid when added in regularly increasing amounts produce a noticeable increase in turbidity, a decided increase in viscosity and quite suddenly a sharp drop to a solution of water consistency. Very shortly after this drop begins visible flocculation occurs, which is reasonable evidence that the process has been accompanied throughout by a continuing decrease in degree of dispersion. But as the degree of dispersion decreases beyond a certain optimum size, the direction of the viscosity curve changes. This shows, therefore, that both an increase and a decrease in viscosity may

TAB. XX. EFFECT OF ADDED SUBSTANCES ON HYDROLYSIS
35 Per Cent Saturated $MgSO_4$ + c c 1-4 H_2SO_4

Glue H ₄	Per Cent of Total N	Glue H ₂	Per Cent of Total N
Control	57.9	Control	72.5
33 per cent $MgCl_2$	67.2	33 per cent $MgCl_2$	74.1
33 per cent KI	65.5	33 per cent aluminum alum.	75.2
33 per cent CH_3COOH	60.9	33 per cent chrome alum.	75.1
33 per cent chloral hydrate	58.7	33 per cent formalin	74.1

accompany a continually decreasing degree of dispersion. It also shows that the degree of dispersion which is optimum for maximum viscosity is not the same as that which is optimum for maximum jell strength.

If the attempt is made to explain the action of those substances which constantly raise or constantly lower the viscosity, it may be expressed in the same terms. Magnesium chloride and chloral hydrate both increase the viscosity constantly. We may assume that the mechanism by which they do this is by decreasing the degree of dispersion. The reason why such high values are obtained with them in contrast to the much smaller maxima obtained by sodium hydrate and acetic acid is probably due to the great velocity of the change in the

⁶See p. 11.

latter cases, which brings the viscosity past its maximum in a very brief interval of time, whereas with the former the change is gradual.

In the case of the nearly regular decreases in viscosity obtained on adding sulphuric and phosphoric acids, there are indications that they pass through a maximum point attained very rapidly on the addition of only traces of the acids, and that further additions produce further decreases in dispersion, but at a rate comparatively slow. Eventually, however, a visible separation of a flocculent precipitate occurs.

The action of potassium iodide appears to be different. In this case the solution resulting from its addition to a glue has a watery consistency, but does not, even on long standing, show any signs of precipitation. The solution becomes less turbid, it filters more readily, the "protective" action of the gelatine on preventing precipitation of insoluble salts becomes markedly less and, in general, it shows to a much greater degree than the control the properties of a molecularly dispersed system. It seems, therefore, reasonable to conclude that the addition of potassium iodide to a glue or gelatine results in an increased degree of dispersion, with the attendant decrease in both viscosity and jell strength.

The last class of substances, e.g., those which have no appreciable effect on viscosity, should, according to our argument, have no appreciable effect on jell strength. This conforms with the results obtained.

STRUCTURE OF GELATINE SOLS

As yet no attempt has been made to define the intramolecular mechanism by which a change in degree of dispersion is brought about, not to speculate upon the specific structure which the colloidal aggregates are assumed to possess. Considerable evidence has been presented in the literature²¹ intending to show the presence of a net-structure in protein solutions. The presence of such a structure would unquestionably reveal itself in producing a high viscosity, for a net structure would offer a considerable resistance to any force involving the deformation of that structure, and viscosity, as it is usually determined, by pouring the liquid through a capillary tube, or by the rotation within it of a suspended disk, would involve such a deformation. This was shown by Garrett²² who found that "the logarithmic decrement of a disk oscillating in a gelatine solution is not a constant, as it is in water or other homogeneous fluids, but, on the contrary, increases as a linear function of the time. This was traced to adhesion between the disk and the protein; if the disk was taken out of the fluid and washed the initial value of the decrement was always the same." He assumed that proteins of the net structure adhered to the oscillating disk.

The writer has shown²³ that mechanical agitation and preliminary heating also decrease the viscosity, and Garrett²² found that in a solution of gelatine which had been boiled the logarithmic decrement of an oscillating disk did not increase with time, but remained constant. These all point to the fact that the net-structure may be more or less destroyed by mechanical agitation and heat, and conversely contribute toward the support of a theory

of an extraordinary structure of some kind in the solutions of gelatine.

But as we are especially concerned here with the relations between viscosity and degree of dispersion, the questions should be considered: What is the internal mechanism by which a change in degree of dispersion, and, consequently of viscosity, is brought about? How is one to regard a change in degree of dispersion when applied to a molecular net-structure? And if such a structure does not satisfy the conditions, what modifications to the theory are necessary?

J. van Bemmelen²⁴ has said: "The formation of flakes which are precipitated in a liquid is dependent on a change in the surface tension of the liquid membranes surrounding the colloid particles, of such type that these membranes between the particles are torn at some point, thus permitting the particles to form aggregates." And W. Ostwald²⁵ states that "the relation of positive to negative surface tension between the disperse phase and dispersion medium determines the degree of dispersion." It has been shown by W. Frei²⁶ that gelatine diminishes the surface tension of water; that the surface tension of a gelatine solution is increased by the addition of small quantities of alkali, and diminished by the addition of small quantities of acid; and that the addition of the anions SO₄, Cl and NO₃ and the cations Na, K, Mg and Ca increase the surface tension of a neutral gelatin solution in the order given. J. Loeb²⁷ has, however, recently shown that all such determinations are valueless unless performed either directly at the isoelectric point (for gelatin $2 \times 10^{-4}N$) or at an exactly determined hydrogen ion concentration above or below this point,²⁸ and in the absence of an excess of electrolyte.

PROTEIN IONS

These investigations establish beyond any doubt the correlation between degree of dispersion and surface tension, but it has also been shown by many workers²⁹ that acids and bases combine with the proteins resulting in the formation of protein ions. The older belief was that these were formed only by the combination of the end -NH₂ and -COOH groups of the polypeptide chains, but an abundance of evidence has been brought to bear against this view, to the end that the -CONH- groups within the molecule are to a preponderant degree responsible for such combination. And not only acids and bases, but also neutral salts have been shown³⁰ to contribute to the formation of protein ions.

We are therefore led to the conclusion that *the addition of electrolytes to a gelatin solution may, and usually does, result in the formation of protein ions, and that the electrical condition resulting within the solution from this ionization produces a change in the relation of positive to negative surface tension between the disperse phase and the dispersion medium, and that this change, in turn, affects directly the degree of dispersion of the disperse phase, or gelatin molecules. The alteration of the degree of dispersion reveals itself*

then in a change in the physical properties, as melting point, viscosity, and jelly strength.

In the light of this rather broad generalization we may speculate upon the probable structure of the colloid aggregates of the protein molecules. There seem to be some difficulties in the net-structure conception. If the molecules are considered as forming only the intersections of this hypothetical "net," and the "connecting threads" being merely lines of force which tend to bring the molecules together, touching each other at certain points, with perhaps a thin film of the dispersion medium between, then, according to W. N. and W. L. Bragg,¹ the conditions would be met for the formation of a crystalline structure. But no such homogeneously built product results. Again, if the molecules be represented as forming both the intersection points and also the connecting threads of the "net," one is put to some trouble to visualize the phenomena attending an alteration in degree of dispersion. If a decrease in degree of dispersion is conceived of as a coalescence, then wherefore should the process become discontinuous with the formation of flakes? If the process consists only of aggregation, then the surface tension phenomena, coming into play, would eventually result in a separation of the dispersion medium from the disperse phase, leaving the system composed of two liquid phases, or a solid and liquid phase, with a clear line of demarcation between. The occurrence of syneresis with solid jells is of course well known, but it is not known to generally occur in the liquid sols.

THREAD-LIKE STRUCTURE

But, as has already been pointed out, there is an abundance of evidence pointing toward some kind of an extraordinary structure in protein solutions, so that we are not permitted to regard them as consisting of discrete particles, of the same nature as true solutions. It seems altogether probable to the writer that the disparities between the behavior of protein solutions² and the proposed theories of structure may be to a great extent harmonized by conceiving the colloid aggregate as of a thread-like, or streptococcal, structure. The latter *similis*³ seems especially to give a clear picture of the situation. The protein molecules may be regarded as the individual cocci, the colloid aggregate as the streptococcal thread. An alteration in the degree of dispersion could now easily be interpreted as consisting of a change in the length of these threads, many uniting to form one, or one breaking into several. If the force tending to unite them were great, cohesiveness⁴ might also become a factor, and as the surface energies between the solute and solvent becomes less,⁵ a flocculent precipitate may result. Indeed Bordet⁶ and Arkwright⁷ both have pointed out that acid agglutination of bacteria belongs to the same class of reactions as the coagulation by hydrogen ions, or electrolytes, of amphoteric colloids. The behavior of the proteins which led to the belief of the existence of a net-structure in their solutions may be explained with equal ease by the streptococcal structure hypothesis, while, in the congealed state, the maze of intermingled threads would readily account for an apparent net-structure. A deformation of this thread-structure would reveal itself similarly in producing an

abnormally high viscosity, and Garrett's⁸ findings that the logarithmic decrement of a disk oscillating in a gelatine solution was not a constant would be explained by an entirely similar manner.

The conception of ionization is especially benefited by the thread-structure conception. Robertson⁹ has pointed out a serious inconsistency in the net-structure theory. He recalls that the viscosity is said to be due to a net-structure, and that it is also attributable, primarily, to the protein ions. This also conforms precisely to the findings of Loeb.¹⁰ Therefore, the net-structure within the protein solution must be built up of protein ions. But, he goes on to say, "such a conclusion is totally out of harmony with the prevailing view that ions, in solutions of electrolytes, are mutually independent and physically discrete bodies, and would appear to invite a distinction between the mode of ionization of ordinary electrolytes and that of protein salts." But if we regard a neutral "streptococcal thread" of protein molecules as capable, by a chemical reaction, of forming a protein salt, and this salt, in turn, of ionization, the identity of the "streptococcal thread" need not be lost, and it is still an independent and physically discrete body, capable of developing osmotic pressure, of conducting the electric current, and, in general, of carrying out the reactions associated with ions in electrolytes.¹¹

It should be added that these threads need not be considered as of great length, except in special cases. A small number of such molecules or ions combined in this manner¹² is sufficient to account for the experimental facts. It is of especial interest to note that Loeb,¹³ in accounting for the ratio of 1:3 in the osmotic pressure of calcium gelatin and sodium gelatin states, "It is in reality only necessary to assume the existence of compounds of the form $\text{Ca}(\text{gelatin})_2$, the two anions of which form one aggregate of two gelatin anions, and to assume further that two, three or more such aggregates of two gelatin anions join to form larger aggregates of four, six, or eight gelatin anions, every one of which keeps its original charge. This would account for all the phenomena observed." Bayliss¹⁴ offered a somewhat similar explanation in accounting for abnormal osmotic pressures with respect to the electric dissociation of solutions of Congo red, namely, "the possibility of aggregated simple ions carrying the sum of the charges of their components."

It is well known, however, that the viscosity of gelatin solutions increases by standing at low temperatures, and, from our knowledge that heating breaks up whatever structure exists, it seems reasonable to expect that this protracted standing at low temperatures may produce the opposite effect, and produce exceptionally long threads, which formation, in turn, is revealed by the high viscosities obtained.

In the light of these reflections it seems reasonable, therefore, to conclude that a modification of the net-structure theory, to the end that the colloid aggregates of protein molecules be considered as united into a "streptococcal thread," accounts somewhat more adequately than the older theories for the several phenomena attendant upon ionization, changes in surface tension, degree of dispersion, viscosity, etc.

To summarize upon the effect of electrolytes on degree of dispersion; and the structure of gelatine sols, it has been shown that:

Glues in general are at their optimum degree of dispersion for maximum jell strength.

Glues are below their optimum degree of dispersion for maximum viscosity.

Whenever a substance is added to a glue which produces a decrease in the degree of dispersion, this change is accompanied by an increase in viscosity until a certain optimum size of molecule has been reached, beyond which point the viscosity falls rapidly.

Whenever a substance is added to a glue which produces an increase in the degree of dispersion, this change is accomplished by a decrease in viscosity.

Electrolytes in general produce a decrease in the degree of dispersion: The hydrogen ion acts very rapidly, the hydroxyl ion acts more slowly, and salts in general act slowly.

FIG. 11. THE RELATION OF NORMAL VISCOSITY TO MELTING POINT

Some salts, e.g., potassium iodide, may produce an increase in the degree of dispersion.

The internal mechanism by which these changes are brought about in the solution is shown to involve ionization of the protein, an alteration in surface tension, and a change in degree of dispersion.

Inconsistencies in the net-structure theory are pointed out, and a modification in favor of a "streptococcic structure" is proposed.

Many methods have been suggested for the determination of the melting point of viscous substances, but few of these appear to have any value in their application to glues and gelatines. Indeed, the change from a firm solid through varying degrees of hydration and phases of viscid semi-mobility to a true colloidal solution are so gradual and uniform that it becomes difficult to apply the term *melting point* at all, even theoretically. In the present paper an attempt is made to establish a satisfactory method for the measurement of *relative* melting points of glues and gelatines, and to determine the relation which exists between this value and the jell strength and viscosity in these substances.

If one may assume as a *measure* of melting point that degree of viscosity at which a glue will no longer flow through the narrow orifice of a viscosimeter tube, then it becomes an easy matter by taking a series of viscosity readings at decreasing temperatures to plot the point at which the rate of flow would be zero. For comparative purposes, however, it should suffice only to plot the values actually obtained and note the relative rates at which the curves tend to approach the vertical (time of flow = infinity). Thus, if the curve of one glue tends to approach the vertical more rapidly than another, as both are reduced through equal intervals of temperature, then the former has the higher melting point.

Working on this principle, two series of glues were selected, those within each series being of the same jell strength but of different normal viscosity. These were examined for viscosity at 5 deg. temperature intervals between 70 and 15 deg. C.

RELATION OF VISCOSITY TO MELTING POINT

The data obtained, when plotted, show unmistakably that the higher the normal viscosity (at 60 deg. C.) of a glue, the more rapidly does it approach the vertical (infinite slowness of flow) with reduction in temperature, which means in the terms of our experiment that the melting point varies directly as the viscosity, or that the viscosity is a function of the melting point.

TABLE XXI RELATION OF VISCOSITY TO MELTING POINT
Concentration, 30 g. glue to 180 g. total weight

Temperature Deg. C.	Grade H ₁	Grade H ₂	Grade H ₃	Grade B ₁	Grade B ₂
70	45.8	47.4	52.0	42.6	46.4
65	45.4	48.0	52.6	43.0	47.0
60	45.8	48.8	53.8	43.2	47.8
55	46.6	49.4	54.8	43.8	49.0
50	47.4	50.6	56.8	44.0	49.6
45	48.0	52.0	59.0	44.8	51.0
40	49.6	54.4	61.8	45.2	52.8
35	50.8	56.8	66.6	46.0	55.4
30	54.0	63.0	79.8	47.6	59.8
25	65.2	139.6	Set	55.2	85.4
20	140.0	Set	Set	70.0	Set
15	Set	Set	Set	Set	Set

Graphical representations of the above are shown in Fig. 11.

In order to determine if the jell strength was also related in any way to the melting point, another series consisting of five glues of uniform normal viscosity but varying jell strength was run in the same manner as above. If the melting point was concerned only with the viscosity at 60 deg. C. and not with jell strength, then the viscosity runs should remain practically constant throughout the changes in temperature and set at the same temperature.

The data obtained show that from 70 deg. to 35 deg. the viscosity remained practically constant throughout the series. At 30 deg., there began to be some divergence, which at 25 deg. became very pronounced, the glues varying in their viscosities at this temperature as their jell strength. At 20 deg. all were too thick to run except the glue with the lowest jell strength.

JELL STRENGTH

It seems, therefore, that the jell strength is also a function of the melting point, but it should be pointed out that the variation due to differences in jell strength at a uniform normal viscosity are not so great as the variations due to differences in viscosity at a uniform jell strength.

A method described by A. Wayne Clark and Louis

Du Bois¹¹ has as its object the determination of "jelly value" in terms of the minimum percentage of glue or gelatine which will remain in solid phase when, after putting into solution and cooling to well below 10 deg. C., it is brought gradually up to 10 deg. C. This appeared to be more of a determination of melting point than of any other physical constant, and so was tried out in an attempt to corroborate the above conclusions.

TABLE XXII. EFFECT OF JELL STRENGTH ON MELTING POINT

Concentration, 30 g. glue to 180 g. total weight					
Number. Jell Strength, Deg. C.	1	2	3	4	5
70	63	64	68	68	70

FIG. 12. THE EFFECT OF TEMPERATURE UPON THE VISCOSITY OF HIDE GLUES

Three sets were run by this method: 1—the standard glues of Grades H₁, H₂, H₃, and H₄; 2—three glues which were of uniform jell strength but varying viscosities;

TABLE XXIII. RELATION OF "PER CENT JELLY VALUE" TO VISCOSITY AND JELL STRENGTH

	No.	Grade	Viscosity	Percentage Glue Added					Per Cent Jelly Value
				2	3	4	5	6	
Standard Grades	1	H ₁	54.0	s	s	s	s	s	2
	2	H ₂	50.8	ss	ss	ss	ss	ss	2½
	3	H ₃	49.4	l	l	l	l	l	4
	4	H ₄	48.0	l	l	l	l	l	5
Uniform jell strength, varying viscosity	1	H ₁	45.6	l	l	ss	s	s	4½
	2	H ₂	49.0	l	l	ss	s	s	4
	3	H ₃	55.0	l	ss	s	s	s	3½
Uniform viscosity, varying jell strength	1	63	46.2	l	l	ss	s	s	5½
	2	64	45.8	l	l	ss	s	s	4½
	3	66	46.0	l	l	ss	s	s	4
	4	68	45.8	l	ss	s	s	s	3½
	5	70	46.2	l	s	s	s	s	3

Note: s=solid; l=liquid; ss=semi-solid

3—five glues which were of uniform viscosity and varying jell strength.

The results show the "per cent jelly value" to vary

inversely with the jell strength in the standard grades, but in the glues of uniform jell strength and varying viscosity there was also a uniform variation, the glue with the highest viscosity remaining solid with the lowest percentage of glue. The glues of uniform viscosity and varying jell strength also varied, the "per cent jelly value" being in inverse ratio to the jell strength.

These results are in every way identical to those obtained by the first method described, and lend additional evidence to the conclusions derived from that set of experiments.

Another method described by C. Frank Sammet¹² has as its object the determination of jell strength by the direct observation of the comparative melting points of the granulated glues. These are soaked in cold water for 1 min., then small amounts placed near the end of a brass strip and the tip of the latter held in water at 40 deg. C. The comparative melting points are noted by observing the order in which the glues melt under these conditions. In order to obtain further confirmation of our conclusions, this method was tried out. The same three series of glues were used as in the previous experiment. The standard grades melted regularly in order of their grade, beginning with the lowest. The glues of equal jell strength and varying viscosities also varied, and regularly, the glues melting in the order of increasing viscosities. But among those glues of equal normal viscosities and varying jell strength, no regular variation could be noted by the method described. Flakes of each glue were then allowed to soak over night in water at 10 deg. C., and small portions of the resulting jell treated as described. The same results were obtained as before. A jelly was then made in 1 to 5 solution and portions of this treated as de-

FIG. 13. THE EFFECT OF TEMPERATURE UPON THE VISCOSITY OF BONE GLUES

scribed. This time the melting point varied regularly in order of increasing jell strength, but this variation was very slight. The reason of failure to obtain a uniform variation in the first two trials was probably due to differences in the thickness and hardness of the par-

¹¹J. Ind. Eng. Chem., vol. 10 (1918), p. 707.

¹²Idem, vol. 10 (1918), p. 595.

ticles and the ease of hydration. No. 4, which melted first, was very thin cut and produced a clear transparent jelly. The others were more firm and opaque.

The final results on this set of experiments are entirely analogous to those obtained by the other methods.

TABLE XXIV. RELATION OF JELL STRENGTH AND VISCOSITY TO MELTING POINT

Standard grades	2	Grade	Jell	Visc.	Order of Melting
	3	H ₁	..	54.0	4th
	4	H ₂	..	50.8	3rd
	5	H ₃	..	49.4	2nd

VISCOSITY AND TEMPERATURE.

In order to ascertain if the viscosity increased proportionately to the decrease in temperature for all glues, all grades of both hide and bone glues were measured for viscosity at temperatures from 150 to 83 deg. F. in the MacMichael viscosimeter.*

An examination of these results, shown in Table XXV, and expressed graphically in Figs. 12 and 13, reveals that in the bone glues the viscosity varies regularly from the highest to the lowest grade at every temperature. In other words, the viscosities are all normal. In the hide glues, however, there is one exception to this, e.g., glue H₁ is of abnormally low viscosity, lower at most temperatures than glue H₂, which it should normally exceed. It will be seen, however, that as the temperature of setting, or melting point, is approached, e.g., at 86 deg. and below, the viscosity of glue H₁ is greater than that of glue H₂, which is what one would expect if jell strength is a function of melting point, as seems to be the evidence of the previous experiments. In all other cases in this series the viscosities are normal at all temperatures.

TABLE XXV. VISCOSITIES OF STANDARD GLUES AT VARYING TEMPERATURES (MacMICHAEL VISCOSIMETER USED)

Temperature Deg. F.	Hide Glues				Bone Glues			
	H ₁	H ₂	H ₃	H ₄	B ₁	B ₂	B ₃	B ₄
150	50	44	29	29	26	25	29	28
140	59	49	33	33	30	28	33	32
130	70	57	37	39	34	30	38	35
120	86	68	42	44	39	36	43	40
110	100	79	46	52	45	42	51	47
105	116	89	52	57	50	45	56	52
100	138	103	59	64	57	50	64	57
95	188	130	70	75	68	60	69	63
90	...	210	100	100	93	75	107	91
88	120	122	112	85	133	104
86	162	155	143	100	165	124
85	205	185	165	110	186	136
83

Many further runs were made of sets having uniform jell strengths and varying viscosities, and of sets having uniform normal viscosities and varying jell strengths, but as these all point to the same conclusions and only

*The viscosity is here measured directly in degrees of angular deflection, and is produced by the torque exerted upon a steel wire supporting a disk suspended in the rotating liquid. See MacMichael, *J. Ind. Eng. Chem.*, vol. 12 (1920), p. 282.

corroborate data already obtained they will not be tabulated.

From these several experiments it seems pertinent to draw the following conclusions upon the relation of melting point to viscosity and jell strength:

If the jell strength remain constant, the viscosity will vary as the melting point.

If the normal viscosity be constant, the jell strength will vary as the melting point.

In normal glues wherein the viscosity varies as the jell strength, the so-called "grade," which is nearly always based primarily upon jell strength, will of course vary as the melting point, but in many glues wherein the viscosity is abnormal to the jell strength the melting point will represent the resultant of those factors which control the viscosity and jell strength, and a "grade" based upon melting point methods would in such cases presumably represent a closer approximation of the true value of the glue than is usually obtained by the present methods."

Inasmuch as it has been shown herein that jell strength and viscosity are both functions of the melting point,* it is suggested that melting point methods be substituted for the customary examinations of jell strength and viscosity in the grading of glues.

As it has further been shown that a measurement of the viscosity at low temperatures" is in effect a measurement of melting point, it is suggested that this method be used, and the MacMichael viscosimeter is recommended as an instrument by which such measurements may be carried out with the greatest degree of speed and accuracy. Such a procedure will also eliminate the necessity of maintaining a set of standard grade glues in the laboratory, as the instrument may be standardized against any common viscid substance." There is thus obtained a decided saving in time, space and labor, a better control of conditions, greater accuracy, and a truer evaluation of product than by the use of the old and time-honored methods.

(Part III, on The Relations Between Physical Properties and Chemical Constitution, and The Influence of Size of Molecule Upon Physical Constants, will be printed in a subsequent issue.)

Use of Sulphur Dioxide in Candy Prohibited in Pennsylvania

Chocolate-covered cherries containing sulphur dioxide have been found offered for sale in the Pennsylvania market. As this is in direct violation of the law pertaining to adulteration and use of preservatives in food, Director Foust of the Pennsylvania Department of Agriculture, Bureau of Foods has taken the matter up with the confectioners' organization in the state and the trade papers calling attention to the fact that the Pennsylvania food laws specifically prohibit the sale of any confectionery containing sulphur dioxide regardless of the quantity.

The majority of the manufacturers have announced that they will use no sulphur dioxide in confectionery sold in this state. The dealers who have not taken this stand will be prosecuted to the limit of the law.

*The final criterion for "grade" must be the strength of the glue in service. For the consideration of this phase of the subject see Part V.

*A discussion of the causes of variation in melting point will be presented in Part III.

*From considerations developed in Part V a temperature of about 90 deg. F., or 32 deg. C., is recommended.

*A 65 per cent solution of cane sugar at 90 deg. F. answers very well.

The Problem of the World's Supply of Energy*

Early Exhaustion of Fossil Fuels Will Require Use of Other Sources; Water, Wind and Sun Power. Continual Increase of CO₂ in Atmosphere Will Reforestate Temperate Zones and Drive Civilization Back to Its Birthplace: Mesopotamia, the Mediterranean, Central America and Peru

By SVANTE ARRHENIUS, PH.D., M.D., D.Sc., LL.D.

SINCE the days of Watt the physical well-being of mankind has become more and more dependent on fossil fuels. The life of today would be impossible without the enormous supply of coal necessary to industrial establishments, for railways and steamships, in the metallurgical arts and for the heating and lighting of our houses. The demand for fossil coal has increased very rapidly, about doubling every ten years during the last century, and is now some 1,200 millions of metric tons per year. It is clear to those who have studied the matter that our coal fields will be exhausted after a certain time. When this calamity will happen, and the probability of the discovery of substitute sources of energy are questions of vital importance.

ESTIMATED LIFE OF COAL FIELDS

One of these questions was answered by the Geological Congress in Canada in 1913. The quantity of fossil coal down to a depth of 1,800 m. would suffice for 6,000 years, at the present rate of consumption, if it were all recoverable, but a very great deal of this coal occurs in beds too thin for profitable working, a considerable part is lost as dust, or left in the mines as pillars, and further, the use of coal will probably increase in the future just as it has done in the past. It is, therefore, necessary to reduce the indicated time considerably, probably to one-fourth, or about 1,500 years.

Of the different countries the United States, in the matter of coal, has the best position, as it has in the matter of other natural resources. The coal treasures there will probably suffice for about two thousand years. The worst situation among the great coal-producing countries is that of England, where the coals will be exhausted within a little less than two hundred years. Germany will be able to meet its demands during a little more than a thousand years.

This time of some few hundreds or thousands of years is very short compared with the time estimate made at the Geological Congress referred to, and only about 1 per cent of the period of man's existence, which probably lies between the thousandth and ten-thousandth part of the time during which life has existed on our earth. It is quite clear that we must soon ration our coal, and substitute as far as possible for fossil fuel other sources of energy.

SUBSTITUTION BY MINERAL OILS IMPROBABLE

It is often suggested that we might use mineral oils as fuel instead of coals. This advice rather reminds one of the words of Marie Antoinette: "If the people complain that they have no bread to eat, why do they not eat cakes." Petroleum is a far more valuable fuel than coal, because it is much easier to transport and to

use effectively. The world's yearly production of mineral oils represents not quite 3 per cent of the energy contained in the yearly production of coal. Petroleum ought, therefore, to be reserved for better purposes, e.g., production of light and lubricants. Further, the recent failure of many oil fields indicates that we must economize this valuable material. According to David T. Day, U. S. Geological Survey, the production per well in the Appalachian oil field decreased from 207 barrels in 1861 to 1.73 barrels in 1907. The production of West Virginia had, in 1910, declined 56 per cent from its maximum output. The oil obtained from the New York and Pennsylvania oil fields fell to 50 per cent from the year 1891 to 1898. If we suppose the present fields of the United States and the present rate of exploration should continue, petroleum would be exhausted by about 1935, and if the present production goes on with no increase, the product would be exhausted in about ninety years, said Charles R. van Hise in 1910, who has done so much to warn against waste in the expenditure of our natural resources. The output of mineral oil has been kept up through an enormous increase in the number of oil wells in each field, and by opening up new fields, e.g., in Oklahoma and California. There are very rich new oil fields in the world which are still not used, or only in a small degree, e.g., in Mexico and Mesopotamia and Turkestan, but certainly they will not last as long as the coal fields, even if the production of this fuel is restrained to but 3 per cent of the simultaneous production of the latter.

Still much less is the hope that sources of natural gas may deliver more than a small fraction of the fuel value of the oil fields. Even peat, although an important fuel, can by no means compete with coal. Thus, for instance, in the United States the available peat is less than one-half of one per cent of the estimated coal. Probably the relative value of the European peat bogs is about the same as compared with the European coal fields. For heating purposes petroleum and peat cannot play an important rôle as compared with fossil coal.

WATER POWER AS SUBSTITUTE FOR COAL

It is very often said that for coal should be substituted the water power of our rivers, often called the "white coal." According to an estimate of Engler, the energy which might be economically taken out from these waterfalls amounts to about 60 per cent of the energy of the present output of coal. But even this figure seems too high, for many of the waterfalls are located in rather inaccessible parts of the world, where no industry is likely to be developed for a long time. So it seems wise to reduce the figure of Engler about 50 per cent. If this is done, it is evident that there is little hope that white coal will be able to substitute for black, except in a small degree. For heating purposes water power

*Delivered through Dr. Allerton S. Cushman in Philadelphia, May 19, 1920, on being awarded the Franklin Medal by the Franklin Institute.

will probably not be used in a noteworthy degree, because used directly for the production of mechanical or electrical energy it is at least three times as valuable as the equivalent quantity of heat. Further, the well-situated waterfalls are already developed in greatest part, at least, in Europe. Thus, for instance, in Switzerland nearly all the waterfalls which have a commercial value are developed, and in a little less degree the same is true in all the other industrial countries of Europe.

ESTIMATED WATER POWER RESOURCES

During the unhappy situation created by the World War, when there was a great scarcity of fuel, and even now, when fuel is extremely expensive, waterfalls were and rapidly are being put to use. Within a short time, therefore, this source of energy will be taken into the service of man, not sensibly diminishing the demand for coal. An estimate of the power of the waterfalls has been made by Koehn and by Keplan, and is of much interest. Although the figures are only approximate, I give them in the accompanying table, with some later corrections. The power is given in millions of horsepower and horsepower per inhabitant:

TABLE. WATER POWER RESOURCES OF THE WORLD

COUNTRY:	Hp. in Millions	Hp. per Inhabitant
Asia	236	0.27
Africa	160	1.14
North America	160	1.17
South America	94	5.25
Europe	65	0.13
Australia	30	3.75
Total	745	Average 0.45
Canada	26	4
United States	100	1
Iceland	2	22
Norway	13	5.2
Sweden	6.7	1.2
Finland	2.6	0.8
Balkan Countries	10	0.6
Switzerland	1.5	0.4
Spain	5.2	0.26
Italy	5.5	0.15
France	6.0	0.15
Austria-Hungary	6.2	0.12
Germany	1.43	0.02
Great Britain	1.0	0.02
Russia	3.0	0.02

These figures are not altogether reliable. Thus, for instance, Leighton gives for the United States 200 millions, and van Hise says: "Others regard this estimate as too high, and say 100 million horsepower is nearer to truth." I think this latter figure is more to be depended on. Van Hise is of the opinion that even it will meet the needs of a population of 250,000,000. Since his estimate made in 1910 the demands for power have greatly increased, and probably only about one-half of the energy given in the table above is available at present without excessive initial expenditures. We may, therefore, assume 0.5 hp. per inhabitant as adequate to present needs. We find then that Europe and Asia are the only parts of the world where water power is really scanty—in Asia the demand is still so small that even this power per inhabitant is more than sufficient. Especially fortunate are those countries, such as South American Republics, and Australia, where water power per unit of population is well beyond this figure, and may be developed at a moderate cost. The United States is among the great powers very well endowed in this regard, as in most other natural sources of wealth, such as metal, ores and coal. In Europe, Iceland ranks first, because of its small population, and the old Saga Island may yet know a new and flourishing era. Then come the Scandinavian countries, the first being Norway, which has already greatly profited through its cheap power, and is destined to be one of the leading industrial

countries of the future. Sweden and Finland possess enough power for their needs. Their waterfalls are not high, and in general are far from established lines of communication, especially from those of the ocean. Denmark has scarcely any water power, as also Holland. Among the other countries of Europe the Balkan States have more power than their industrial needs require. Switzerland may also be regarded as having a nearly sufficient supply of water power, which is the more fortunate, as this highly industrial country does not own any coal deposits. The same is true of the new Austria, which has lost its old coal districts but has retained by far the greater part of the waterfalls of the old Austria, so that it now probably ranks with Switzerland in this respect. Spain is also a relatively well situated state, but which up to the present has not made much use of its resources. In general, the waterfalls in the Alps, Spain, Italy and the Balkans are high and of great value. For the industries of France and Italy water power is of the greatest importance, although it must be regarded as insufficient for nations so highly developed. At the end of the list come the three great powers of Great Britain, Germany and Russia, with only a fiftieth horsepower per inhabitant. Russia is an agricultural country, with a very small demand for power, and agriculture will probably remain its chief industry because of its small power resources, both in coal and water. England and Germany, now the most highly developed industrial countries in the world, will undoubtedly also, in the future have agriculture for their chief industry. Probably a great part of these countries will again be covered by forests, as they were in the time of Tacitus.

It is often asserted that the power of tidal waves should be utilized. Of course, this is possible, but doing so on a large scale would involve an initial investment not justified by prices likely ever to be obtained for power. The energy of the tidal wave is so widely distributed along the shores of the oceans that it is impossible to commercially collect a sensible part of it. It is quite in contrast to the energy of fossil fuel and waterfalls.

SOLAR ENERGY ACCUMULATED IN PLANTS

All available energy on the earth has its origin in solar radiation. Of this energy a small part, 0.12 per cent, is accumulated in vegetation, which, however, is great as compared with the energy of the coal burned in the industries. A detailed calculation, made by Prof. Schroeder, of Kiel, shows that about twenty-two times as much energy is yearly accumulated in plants as is represented by the coal consumed in the same time. Of this energy in vegetation 67 per cent is taken up by the forests, 24 per cent in cultivated plants, 7 per cent in the grass of the steppes and 2 per cent on desert lands. The energy collected by forests may be used for heating purposes, and exceeds every year that of the coals burnt by about fourteen times. But, unhappily, the greater part of this energy is collected in tropical areas, and the highly cultivated countries are so nearly deforested that their production of wood is not nearly sufficient as fuel for their industries. Further, the wood produced in civilized countries is needed for the production of paper, pulp and lumber. In forest lands the refuse from the woods may be sufficient for domestic purposes, and during the war even the industrial needs of certain countries for combustibles were met by wood, where the importation of coal was hindered by the

blockade. The costs, however, were very high, due to the expensive transport from the forests to the industrial centers. The transport of wood from the immense forests in the tropics to industrial countries seems impossible on economic grounds. The forest lands possess, therefore, an advantageous position in this regard. Before other industrialized countries will be able to substitute wood for coal an economic solution of the transportation problem is necessary, which at present seems fraught with exceedingly great difficulties.

POWER FROM WINDMILLS

Two other sources of energy, greatly dispersed in form, remain to be considered, namely, those of the winds and of sunshine. They are extremely great, and exceed that of simultaneous burnt coal from 5,000 to 70,000 times, respectively. The energy of the winds is taken up by windmills, which have been in use in Europe since the eleventh century. The great objection to wind as a source of power is its variability, and the high installation costs per unit of power continuously deliverable. It has been proposed to store the energy of the wind by means of accumulators, charged from windmills, and to use these accumulators during times of calm. But even in windy countries, e.g., Denmark, this method is extremely uneconomical, as compared with coal or wood at their present price. Windmills are widely used for pumping water, both in the New and the Old World.

SOLAR ENERGY

The radiation of the sun may be concentrated by means of mirrors on a boiler, and this connected to a steam engine. The best known of these solar engines was constructed by John Ericsson, and described in *Nature* in 1888. It was an improvement of an earlier machine constructed in 1860. In his experiments in New York, John Ericsson obtained an effect of one horsepower with a mirror of 10 sq.m. opening. Later, his experiments were taken up on a commercial scale by Mr. Shuman, of Philadelphia, who installed a solar engine, with mirror of 1,200 sq.m. in all, at Meads, 10 km. south of Cairo, in Egypt. The machine was of the Ericsson type, with some small modifications, and auxiliary apparatus. Shuman did not obtain more than half the effect of that obtained by Ericsson, namely 1 hp. per 20 sq.m. mirror opening. After an inspection of Mr. Shuman's plant, Mr. Ackerman thought it possible to introduce improvements which would give as good results as those obtained by Ericsson.

FUTURE OF SOLAR ENGINES

After improvements the solar engine seems likely to play an important rôle in the opening up for cultivation of great arid districts in tropical countries, as Ericsson maintained with great energy it would do. In these parts of the world are great deserts, such as Sahara, the Arabian desert, the Syrian desert, and those in Mesopotamia, which have in historical times been the seat of flourishing culture, but are now the home of wandering tribes. The decay of these regions resulted from the destruction of their aqueducts and irrigation plants, which the present wandering population is unable to restore. With the aid of the solar machine it would be possible to re-establish the old agriculture and horticulture of these districts, and industrial works founded on its use might also be looked forward to. It is not only in the deserts that the sun in shining nearly continuously during the greatest part of the year, but ex-

tensive provinces in Spain, Greece and North America possess such a climate that they would profit by the introduction of the solar engine. In other parts of the world, where the sky is covered for the greatest part of the year, as in the Congo or the Amazons, or which lie nearer to the poles, as the temperate regions, the solar machine will be of very little use.

PROBABLE RESULTS OF TOTAL CONSUMPTION OF COAL

It seems very probable that when fossil fuel has been consumed, civilization and culture will return to its birthplace about the Mediterranean and in Mesopotamia in the Old World, and to Central America and the land of the Incas in the new.

According to some calculations made by me an increase of the carbonic acid in the atmosphere will give the whole earth a more uniform and warmer climate. Therefore, we may suppose that the burning of coal will cause our climate to approach to that of the tertiary age. Furthermore, vegetation is highly stimulated through absorption of carbonic acid in the soil, augmented through an increase of the carbonic acid in the air. It is, therefore, probable, as I have tried to show in my book, "World's in the Making," that the total consumption of the available coal by the industries will, in a high degree, favor agriculture and the growing of forests in the temperate regions now the chief seat of culture. These regions will then know not only harmful, but some useful consequences as the result of the present waste of our fuel resources.

Stockholm, Nobel Institute.

Thermo-Electricity Progress

Prof. C. A. F. Benedicks, of Stockholm University, delivered a lecture on "Recent Progress in Thermo-Electricity" before the Institute of Metals, June 10, 1920. He first gave a short summary of his theoretical views upon the metallic conduction of electricity which explained many matters not made clear by the former electron theory. A consequence of this new theory was that one has to conclude that even in a single homogeneous metal thermo-electric currents do occur; hitherto such currents were believed to be produced only when two different metals were present. Prof. Benedicks gave a concise demonstration of the most important experimental evidence of the truth of this conclusion, utilizing for this purpose various metals.

In liquid mercury it had been possible for him definitely to prove the existence of thermo-electric currents, thus disproving the negative results of previous workers. A consequence of what the lecturer termed his "homogeneous thermo-electric effect" was that there must exist the *reverse* effect, the "homogeneous electro-thermic effect," including as a special case the well-known Thomson effect. The reality of this effect was duly made clear. A specially interesting demonstration was of a new rotating thermo-electric apparatus made entirely of copper and rotating in a magnetic field, the driving force originating solely from unequal heating (by means of a tiny gas jet) of thin strips of copper.

The point at which the new knowledge brought forward by Prof. Benedicks might have some practical interest lay in the possibility of reducing the thermal conductivity of metals by insulated subdivision into fine wires without impairing the electrical conductivity. The demonstrations were carried out with the aid of a galvanometer provided by the Cambridge & Paul Instrument Co.

Characteristics of Primary Low-Temperature Tar

By FRANZ FISCHER*

IT IS desirable to have an easy method of distinguishing light, primary tar from ordinary tar. Today many wholly useless products are given out as genuine primary tar which in reality have nothing to do with the true low-temperature tar. It is possible, however, that with the characteristics of this tar which we now give, not all of the numerous points of difference are established finally, through which a high-grade primary tar passes from a useless, thick, pitch-like, ordinary tar of the vertical retorts, generators, cokeries and ovens. It is possible too, that a further definition of the given conditions for primary tar may be necessary.

The following characteristics must be required of a good quality of the genuine tar in general:

1. It must be liquid at room temperature; at the most a separation of small amounts of paraffine may influence its ready fluidity.

2. Its specific gravity at 25 deg. C. must correspond to 0.95-1.06.

3. On a thin layer it is a golden red to port wine colored oil.

4. In the fresh state it smells nearly always of sulphuretted hydrogen or sulphide of ammonium. In no case should it smell of naphthalene.

NAPHTHALENE TEST

Low-temperature tar, if rightly prepared at moderate temperatures, contains no naphthalene. Naphthalene is a secondary product obtained first at 750 deg. C. and above. A tar, therefore, which contains naphthalene has been heated to a higher temperature than that employed for the production of primary tar. The simplest method of distinguishing them is based upon these facts. At the high temperature at which naphthalene is obtained primary tar is altered in constitution. It contains, as we know, among its constituents paraffine, olefines, naphthalene, phenols, and, only in small proportion, aromatic hydrocarbons. To the first four constituents it owes its low specific gravity, and these four constituents are converted at temperatures higher than 550 deg. C., in great measure, into aromatic compounds by which a rise in specific gravity is caused. Upon these facts is grounded a second method of distinguishing primary tar from ordinary tar.

THICKENING POWER

If naphthalene is not found, a finer method is required. On the one hand, naphthalene-free tar is not always primary tar, since overheating is not always carried to such a degree that naphthalene is formed; then a naphthalene-free tar may be overheated. A process to distinguish between them is based upon the solubility power of the individual constituents of the tar and their specific gravity.

The hydrocarbons afford a suitable means of following this process, since the phenols are not adapted for the purpose, because the quantity of phenols in the tar is subject to great variations, according to the kind of coal used. We propose, in the next place, to shake up the tar in petroleum spirit, and then separate the pitch and asphalt constituents; the petroleum spirit solution is then freed from acid compounds by alkali and distilled

at 200 deg. C. The oil which goes over at temperatures from 200 to 300 deg. C. is separated and taken up, and from the distillate and residue the specific gravity is determined. With primary tar the distillate of 200-300 deg. C. is below 0.90 at 20 deg. C. With other tars, it is nearly 1 or over. The residue obtained by boiling at 300 deg. C., is, in the case of primary tar, thick, like paste, owing to the separation of paraffine; it is completely soluble in petroleum spirit and ether, and at 50 deg. C. has a specific gravity below 1. The residue obtained in a simpler manner by boiling overheated tar at 300 deg. C. dissolves, after distillation of the 200-300 fractions, only partially in cold petroleum spirit, leaving a residue of solid matter. This residue, also, is not completely soluble in ether, and has at 50 deg. C. a specific gravity of over 1—that is, it sinks in water at 50 deg. C.

SAMPLING

Technical primary tar to the amount of 300 c.c. was thoroughly shaken in a flask for several minutes with 300 c.c. of petroleum spirit. The brownish-yellow red solution was then poured off from the separated dark viscous mass, and shaken up with 200 c.c. of 5N (20 per cent) soda lye in a glass arm. The soda lye was then drawn off, replaced by an equal quantity of fresh lye, shaken up again, and separated. The petroleum ether solution was washed with an equal quantity of water and separated. To remove all traces of water, it was filtered, the petroleum spirit evaporated from a small flask over the water bath until no more went over. The residue was then freed from all fractions boiling at 200 deg. C. or over, in a flask over an asbestos plate, and after filling up a still smaller flask of about 100 c.c. capacity, it was distilled off in a flame at 300 deg. C. The distillate of 200-300 deg. C. then corresponded to about 20 per cent of the residue.

The values thus obtained are given in the following table:

	Technical Tar	Vertical Retort Tar	Mond's Gas Tar
Sp. gr. (20 deg. C.) of fraction 200-300 . .	0.9100	0.9850	0.9306
Sp. gr. (50 deg. C.) of the residue boiling above 300 deg. C.	0.9606	1.0931	0.9713

The residues obtained by distillation of the primary tar and Mond's or oven gas tar were thickened to a soapy character by separation of the paraffine. Both were readily dissolved in ether and petroleum spirit in the cold. By rubbing up a sample with an equal volume of acetone the paraffine could be separated in the form of white flakes. The residue of vertical retort tar showed, in comparison with primary tar, a quite minimal separation of paraffine in the form of a thin film and left behind after rubbing up with petroleum spirit the greater part of its substance in the form of a brown, insoluble mass. Ether left a very dark, flocculent mass undissolved.

We examined such a product. The sample failed to show the characteristics No. 3, as the tar remained wholly black. But the naphthalene test showed that it contained no naphthalene. Specific gravity, however, proved that it belonged to primary tar, in which only the lower fractions were wanting.

A sample was obtained from a Breslau gas works. Externally this tar resembled a good quality of primary tar, showed a relatively great fluidity, no smell of naphthalene and the golden red so characteristic of primary tar. But the sp. gr. of 1.084 distinguished it from primary tar as did the positive naphthalene test, its behavior to petroleum spirit.

*Translated from *Zeitschrift für angewandte Chemie*, 1920.

Permeability of Rubber to Gases—II

Relative Permeabilities to Hydrogen of Oxygen, Nitrogen, Argon, Air, Carbon Dioxide, Helium, Ammonia, Ethyl Chloride, Methyl Chloride and Water Vapor—Factors Summarized and Data Tabulated*

By JUNIUS D. EDWARDS AND S. F. PICKERING

ON DETERMINING the permeability of rubber to different gases it is preferable to refer the values to some standard rather than attempt to express the permeability in absolute units. In this work, the permeability to hydrogen has been adopted as the standard rate because hydrogen is so generally used for filling balloon envelopes and because the greatest part of our knowledge of the permeability of rubber to gases concerns hydrogen. Accordingly, the permeability to hydrogen of any sample of rubber has been set equal to unity; its permeability to any other gas is given as the ratio of its permeability to that gas to its permeability to hydrogen. In order to secure the required precision it has been necessary to determine the permeability of every test piece, both to hydrogen and to the gas in question.

The hydrogen used in all this work was made in a Kipp generator from a very pure lot of zinc and from c.p. hydrochloric acid. It was purified by passage over soda-lime and anhydrous granular calcium chloride. Conclusive tests made in another connection, on hydrogen generated in this way, showed it to contain not more than 3 or 4 parts in 10,000 of impurity when the generator was properly swept out.

It was found that the ratio of permeabilities for different gases with different samples of rubber was fairly constant—sufficiently so to make the results of interest and value. In all probability the ratio varies somewhat with different samples of rubber; the extent of this variation is indicated roughly by the concordance of the results secured with different samples. In a preceding section a first approximation to the specific permeability of rubber to hydrogen was given; this value multiplied by the ratio of permeabilities of different gases will give approximately the specific permeabilities of those gases.

PERMEABILITY OF RUBBER TO OXYGEN

It is an interesting fact, first pointed out by Graham, that rubber is more permeable to oxygen than to nitrogen. As a result, air which has passed through rubber contains a higher percentage of oxygen than normal air. The significance of this fact in connection with the use of rubber-coated balloon fabrics has already been discussed by one of us.

The permeability of rubber to oxygen was determined with the apparatus of Fig. 1 with some appropriate minor changes. A current of oxygen was passed over one side of the fabric and hydrogen over the other side. The oxygen passing into the hydrogen was deter-

mined with the interferometer, using hydrogen from the same source as the standard of comparison. The oxygen was analyzed volumetrically. The results were corrected to a partial pressure of 100 per cent; the existing partial pressure of oxygen was 99.55 per cent.

The results of a series of tests are shown in Table I. The average ratio of permeabilities, oxygen to hydrogen,

TABLE I. PERMEABILITY OF RUBBER TO OXYGEN AND HYDROGEN

Fabric No.	Permeability to Oxygen Liters per sq. m. per 24 Hr.	Permeability to Hydrogen Liters per sq. m. per 24 Hr.	Ratio of Permeabilities Oxygen: Hydrogen
50.313	5.09	11.83	0.430
50.313	5.16	11.91	0.433
50.313	4.84	10.81	0.448
50.313	4.97	10.77	0.461
50.313	4.82	11.06	0.435
50.313	5.30	11.52	0.460
Average.....			0.445

is about 0.45. For this ratio Graham found the value 0.466 and Dewar's curves show a value of 0.500 at 25 deg. C.

PERMEABILITY OF RUBBER TO NITROGEN

The permeability of rubber to nitrogen was determined in the same way as the permeability to oxygen except that nitrogen was used in place of oxygen. The results of these experiments are given in Table II; the

TABLE II. PERMEABILITY OF RUBBER TO NITROGEN AND HYDROGEN

Fabric No.	Permeability to Nitrogen Liters per sq. m. per 24 Hr.	Permeability to Hydrogen Liters per sq. m. per 24 Hr.	Ratio of Permeabilities Nitrogen: Hydrogen
50.313	1.48	8.77	0.169
50.313	1.53	9.47	0.162
50.313	1.45	9.14	0.159
50.313	1.38	9.10	0.152
50.313	1.51	8.76	0.172
50.313	1.27	9.08	0.140
50.313	1.44	9.41	0.153
50.313	1.52	8.73	0.174
Average.....			0.160

average ratio of permeabilities, nitrogen:hydrogen is 0.16. Graham gives the value 0.18 and Dewar's value is 0.12 (at 15 deg. C.).

PERMEABILITY OF RUBBER TO ARGON

No experiments with argon were made in the course of the present work because a satisfactory sample of argon was not available. For the sake of completeness, reference will be made to the work of Dewar and of Rayleigh with argon. Dewar found the ratio of the permeabilities to argon and to hydrogen to be $\frac{1.28}{15.6} = 0.082$ at 15 deg. C. Rayleigh found that in a sample of "air" which had diffused through rubber there was 1.93 per cent argon in the nitrogen after removing

*This paper, of which part I was published in *CHEM. & MET. ENG.*, vol. 28, No. 1, July 7, 1920, is a condensation of a comprehensive report to be issued by the U. S. Bureau of Standards.

¶*Phil. Mag.*, vol. 49, p. 220; 1900.

the oxygen. Atmospheric nitrogen contains $\frac{0.94}{78.12} = 1.20$ per cent argon. He therefore concluded that rubber was somewhat more permeable to argon than to nitrogen. The ratio of permeabilities, argon : nitrogen, calculated from his original data is 1.6. Using the value we have found for the ratio nitrogen : hydrogen, the ratio argon : hydrogen would be 0.26.

PERMEABILITY OF RUBBER TO AIR

The permeability of rubber to air can be calculated from its permeability to oxygen and nitrogen by means of the proportionality between permeability and partial pressure. According to Sir William Ramsay the composition of air is as follows: Nitrogen, 78.12 per cent; oxygen, 20.94 per cent, and argon, 0.94 per cent. The permeability of rubber to air (referred to hydrogen) would then be

$$P = (0.7812 \times 0.16) + (0.2094 \times 0.45) + (0.0094 \times 0.26) = 0.22$$

In confirmation of this value, the permeability to air was determined directly by the same method used in the case of oxygen and nitrogen. The refractivity of the air which had diffused through the rubber was calculated from the composition as determined by typical analyses. The influence of any probable variation in composition is negligible. The results are given in Table III. Though the data are few in number and not very concordant, the average ratio, 0.23, is in close agreement with the value (0.22) which was just calculated.

TABLE III. PERMEABILITY OF RUBBER TO AIR AND HYDROGEN

Fabric No.	Permeability to Air Liters per sq. m. per 24 Hr.	Permeability to Hydrogen Liters per sq. m. per 24 Hr.	Ratio of Permeabilities Air : Hydrogen
50,313	2.21	9.45	0.234
50,313	2.14	8.73	0.245
50,313	1.97	9.40	0.210
Average.....			0.230

The composition of air which has diffused through rubber is a matter of interest. This may be calculated from the permeability to nitrogen, oxygen and argon and their partial pressures. The composition thus calculated is as follows:

	Per Cent		Per Cent
Nitrogen	56.8	Argon.	0.9
Oxygen	42.3		100.0

Graham found as much as 41.6 per cent oxygen in air which had diffused through rubber; Edwards and Ledig¹ found 41 per cent.

These facts are of obvious practical importance in many instances.

PERMEABILITY OF RUBBER TO CARBON DIOXIDE

In determining the permeability to carbon dioxide, the regular method with the interferometer was employed. The carbon dioxide was generated from marble and hydrochloric acid and passed over anhydrous sodium carbonate and calcium chloride. Volumetric analysis showed the presence of 99.9 per cent carbon dioxide. The results of a series of these tests are shown in Table IV. Each permeability value recorded in the table is the average of three to six separate observations on the same test piece.

¹"Significance of Oxygen in Balloon Gas," *Aviation and Aeronautical Eng.*, vol. 6, p. 325; 1919.

TABLE IV. PERMEABILITY OF RUBBER TO CARBON DIOXIDE AND HYDROGEN

Fabric No.	Permeability to Carbon Dioxide Liters per sq. m. per 24 Hr.	Permeability to Hydrogen Liters per sq. m. per 24 Hr.	Ratio of Permeabilities Carbon Dioxide : Hydrogen
50,313	27.3	9.6	2.84
50,313	28.6	9.7	2.95
Dental dam	42.4	14.0	3.03
26,293	27.0	9.2	2.94
26,293	26.6	9.5	2.80
Average.....			2.91

The values obtained for the permeability of fabric No. 50,313 to hydrogen and carbon dioxide in the partial pressure experiments recorded in a previous section may be used to obtain a value for this ratio, even though the determinations with hydrogen and carbon dioxide were not made with the same test pieces. The average of seven determinations with hydrogen was 9.71 liters and the average of seven determinations with carbon dioxide was 27.86; the ratio is 2.87, which is in substantial agreement with the ratio 2.91 found in Table IV. It may be concluded that rubber is approximately 2.9 times as permeable to carbon dioxide as to hydrogen.

Values found by other experimenters for this ratio are of interest. Graham² gives 2.47 as the ratio (temperature not specified). Kayser³ gives equations for the variation of permeability with temperature; the ratio of the permeabilities of rubber to carbon dioxide and hydrogen at 25 deg. C., as calculated from these equations, is 2.48. Dewar,⁴ using thin films of rubber under tension and having a thickness of about 0.01 mm., found a value of 2.5 for this ratio at 15 deg. C. In another series of experiments at "ordinary temperatures" Dewar found, for the same film, a relative rate of $\frac{30.0}{8.4} = 2.8$.

PERMEABILITY OF RUBBER TO HELIUM

A knowledge of the permeability of rubber to helium is of great importance at the present time because of the recent development by the U. S. Government of a supply of helium for filling airships. The investigation of the permeability of balloon fabrics to helium was made for the Bureau of Steam Engineering of the Navy Department.⁵ The helium employed was furnished by that Bureau and was contained in a steel cylinder under 1,800-lb. pressure. Its composition, as determined by our analysis, was as follows:

	Per Cent		Per Cent
Helium.....	94.6	Methane.....	0.2
Nitrogen.....	5.2		100.0

The methane in the gas was determined by combustion with oxygen. The density of the gas was then determined with the Edwards gas density balance and the composition calculated on the assumption that the residue was nitrogen and helium. Oxygen was tested for and shown to be absent. To confirm the analysis a direct determination of nitrogen was made by absorption with metallic calcium. This method showed approximately 5 per cent nitrogen. When the gas was examined spectroscopically, neon and argon were found to be either absent or present in such small amounts as to be masked by the other gases present. Accordingly, it is thought that no appreciable error was

²*Phil. Mag.*, vol. 32, p. 401; 1866.

³*Wied. Ann.*, vol. 43, p. 544; 1891.

⁴*Proc. Roy. Inst.*, vol. 21, p. 813; 1915.

⁵*Proc. Roy. Inst.*, vol. 21, p. 559; 1915.

introduced by the assumption that the residue consisted of helium and nitrogen. The refractivity of the mixture as determined with a Zeiss-Rayleigh interferometer indicated an amount of helium within 0.3 per cent of the value shown by the above analysis.

The amount of helium penetrating the fabric was determined with the interferometer in the usual way. Because of the large difference in the refractivities of air and helium, $(2917 - 342) \times 10^{-7}$, the interferometer furnished a very sensitive means of determining helium. Each scale division indicated about 0.004 per cent helium in air; the total amount present could be determined with that precision.

The observed permeability obtained with the gas containing 94.6 per cent helium was corrected to the standard condition; that is, a difference in partial pressure of 100 per cent helium on the two sides of the fabric. This was done by multiplying the observed

permeability by the ratio $\frac{100}{94.6 - x}$ where x is the percentage of helium (usually about 0.4 per cent) on the "air side" of the fabric.

In Table V are given the permeabilities to helium and hydrogen of a number of samples of different fabrics. The fabrics tested are from three different manufacturers and include both envelope and ballonet fabrics. Although there was considerable variation in the relative permeabilities, this variation could not be entirely ascribed to experimental error. It seems probable that part of this variation is due to differences

TABLE V. PERMEABILITY OF RUBBER TO HELIUM AND HYDROGEN

Fabric No.	Observed Permeability to Helium Liters per sq. m. per 24 hr.	Permeability Corrected for 100% Helium Liters per sq. m. per 24 hr.	Observed Permeability to Hydrogen Liters per sq. m. per 24 hr.	Ratio of Permeabilities Helium: Hydrogen
27,145	9.6	10.2	16.1	0.63
45,847	9.8	10.5	15.7	0.66
45,855	7.6	8.0	14.0	0.57
35,858	7.4	7.9	13.7	0.58
36,827	6.4	6.8	10.0	0.68
36,827	6.7	7.0	10.6	0.66
36,827	6.5	6.9	10.7	0.64
36,828	6.2	6.6	10.6	0.66
36,827	6.6	7.0	10.6	0.66
36,827	6.1	6.4	9.5	0.67
36,827	6.3	6.7	9.3	0.72

26,295	5.7	6.1	9.8	0.62
24,579	4.8	5.1	8.7	0.59
Average				0.65

in the relative permeabilities of different fabrics to these gases. The average ratio of 0.65 appears satisfactory for present purposes.

The other values for this ratio which appear in the literature are those of Dewar¹⁰ and Barr¹¹. Dewar

found a ratio of $\frac{1.75}{5.6} = 0.31$.

No information is given regarding the helium used. Barr estimated two-thirds of the permeability to hydrogen—a value which is in agreement with ours.

PERMEABILITY OF RUBBER TO AMMONIA

Ammonia has been considered as a filling gas for balloons. Its specific gravity is only 0.596 and it offers advantages from the standpoint of freedom from fire hazard and the fact that it can be transported in the liquid form. However, the fact that rubber is quite

permeable to ammonia would necessitate the use of a different type of fabric for the balloon envelope.

In determining the permeability of rubber to ammonia it was necessary to use a special permeability cell made of steel, which would be unattacked by the ammonia. All connecting tubes coming in contact with the ammonia were either steel or glass. The ammonia which passed through the fabric into the air stream was absorbed in a measured volume of tenth-normal sulphuric acid and the excess acid determined by titration. Two small wash bottles were always used in series but never more than a negligible amount of ammonia escaped absorption in the first wash bottle. Two sets of wash bottles were used and they were connected to the cell alternately through a three-way cock. They were attached to the system by a mercury seal so that

they could be easily detached. Each value recorded in the table is the average of a number of observations each covering a half-hour period.

The ammonia was taken from a small steel cylinder, which had been evacuated to a very low pressure before filling with liquid ammonia. The gas can be considered to be free from air and water vapor; in fact, the total amount of impurity in this sample, which was carefully purified by fractionation, was shown by tests of C. S. Taylor of this Bureau to be less than 1 part per 100,000. The results of a series of experiments is given in Table VI. The average ratio of the permeability to ammonia and hydrogen is probably very close to 8.0.

PERMEABILITY OF RUBBER TO ETHYL CHLORIDE

An interferometer of the portable type was used for determining the percentage of ethyl chloride passing through the fabric into the air stream. The ethyl chloride was contained in a glass flask fitted with a steel valve and the vapor could be readily withdrawn under

its own pressure. It was prepared by C. S. Taylor of the Bureau of Standards, from very pure materials, and further purified by fractionation. The total impurity in the vapor phase was undoubtedly less than 1 part in 10,000, a purity far beyond that required for the present work.

¹⁰Loc. cit.

¹¹Barr. British Advisory Comm. for Aeronautics, 1915.

The permeability of rubber to ethyl chloride, as shown by these few tests, is approximately 190 to 200 times its permeability to hydrogen.

PERMEABILITY OF RUBBER TO METHYL CHLORIDE

For the purpose of comparison with ethyl chloride, the permeability of rubber to methyl chloride (CH_3Cl) was also determined. The interferometer was employed

in estimating the percentage of methyl chloride in the same manner as with ethyl chloride. The sample of methyl chloride used had been carefully purified by fractionation by C. S. Taylor. Three tests were also made with a sample of methyl chloride the purity of which was unknown. These gave a ratio of permeabilities, methyl chloride to hydrogen, of 16.8, 17.6 and 17.8, but they are not included in the average. The other results are given in Table VIII. The permeability of rubber to methyl chloride is approximately 18.5 times its permeability to hydrogen.

PERMEABILITY OF RUBBER TO WATER VAPOR

The permeability of rubber to water vapor is interesting for a number of reasons. In view of the popular

conception of rubber as a "waterproof" material it might be thought that it was quite impermeable to water vapor whereas the opposite is true—its permeability is relatively high. This fact is of great importance in many instances where rubber is used as a gas container, such as, for example, the use of rubber tubing in chemical and physical work. The use of rubber con-

nections in any apparatus where the water content of the gas is important may introduce errors.

The high permeability of rubber to water vapor renders its determination rather difficult. The first method employed in its determination was to pass a current of air saturated with water vapor at a temperature slightly below 25 deg. C. over the fabric, which was maintained in the cell at 25 deg. C. A stream of air, previously dried over phosphorus pentoxide, was passed over the other face of the fabric and thence through an absorption tube filled with phosphorus pentoxide in which the water vapor could be absorbed and weighed. The results were very erratic, probably because of the low partial pressure of the water vapor in the air (about 3 per cent) and the large effect on the difference in partial pressure produced by small variations in the rate of passage of the dry air. The

results, however, are confirmatory of those secured by the following method:

A shallow crystallizing dish, 8 cm. in diameter, was partly filled with phosphorus pentoxide and the top closed by a sheet of rubber, such as dental dam, which was fastened at the edge with rubber cement. The dish was then placed in an atmosphere saturated with water vapor and the rate of increase in weight determined. The results are shown in Table IX; obviously, they only give an approximate figure and no claim of accuracy is made for them. Lack of time prevented carrying this phase of the work farther. In connection with this table and the succeeding one, attention should be called to the fact that the permeability to water vapor is calculated for the assumed case of a difference in partial pressure of water vapor of 760 mm. This is done to make the results comparable with the hydrogen value. In any test the partial pressure of water vapor was about 20 mm.

A few experiments were also made with liquid water in contact with the rubber film. In these tests, instead of cementing the rubber to the dish containing the phosphorus pentoxide, the rubber was cemented to the top of another exactly similar dish from which the bottom had been removed. The edges of both dishes were ground plane. The dish with the rubber film across the bottom was partially filled with water and placed on top of the dish containing the phosphorus pentoxide. When it was desired to weigh the lower dish, the upper dish was replaced by a watch glass. The results of these tests are shown in Table X. In calculating the results the partial pressure of water vapor used was that corresponding to the temperature of the water in contact with the rubber.

According to these few tests the permeability of rubber to water vapor is about fifty times the permeability to hydrogen when saturated air is in contact with the rubber and about 100 times when liquid water is in contact with the rubber. In these methods diffusion processes were depended on to bring the water vapor into contact with the rubber and from the rubber to the phosphorus pentoxide. This factor should tend to give low values. The accidental errors of handling and weighing would probably be in the opposite direction.

THEORY OF PERMEABILITY

One object of this investigation was to establish, if possible, a quantitative relationship between the permeability of a film of rubber to any particular gas and the various factors on which it is dependent. Only the part of the program detailed in the preceding pages was completed, however, before it became necessary to discontinue the work.

A simple and satisfactory picture of the process is one of dynamic equilibrium in which the gas is dissolved at one side of the rubber at a rate proportional to its solubility and partial pressure, and diffuses through the rubber where it evaporates from the other side. The same process takes place in the opposite direction so that the net transference of gas is proportional to the difference in the partial pressures at the two faces of the rubber. Because of the lack of data it is not feasible to analyze the relations between solubility and rate of diffusion through the rubber. The permeability in every case investigated increases rapidly with increase of temperature. According to Kayser² the solubility of both carbon dioxide and hydrogen decreases with increase of temperature. If this be true there must be a rapid decrease in the internal resistance of the rubber to the passage of the gas, because the ordinary temperature coefficient of gaseous diffusion is unable alone to account for the facts.

A rough parallel, with notable exceptions, may be drawn between the permeability of rubber to different gases and to the boiling points of the gases. In general, the higher the boiling point of the gas the greater the rate at which it penetrates rubber. The specific chemical characteristics of the gas and of the rubber colloid determine, however, the solubility, rate of penetration, etc., and not enough is known of them at the present time to warrant further speculation. There are, however, many interesting fields of investigation opened by this work, and the results should be extremely useful in the many cases where the behavior of rubber in contact with gases is concerned.

SUMMARY

Certain of the factors which determine the permeability of rubber to gases have been investigated and the relative rates of penetration of a number of gases determined. The major findings are summarized as follows:

1. The permeability of rubber compounds varies with the composition as would be expected. The aging of rubber films is accompanied by a decrease in permeability; a similar decrease may be effected by over-vulcanization. The rubber, which shows a very low permeability for these reasons, is usually very much deteriorated and frequently brittle, so that it is a disadvantage from the standpoint of gas-tightness.

2. The permeability to any gas is found to be directly

proportional to its partial pressure provided the total pressure is constant. The variation of permeability with total pressure depends on the thickness of the rubber, the way in which it is supported, etc.

3. The permeability to hydrogen is inversely proportional to the thickness of the rubber. No other gas was tested in this respect.

4. The specific permeability to hydrogen at 25 deg. C. of vulcanized rubber similar to the grade known as dental dam is about 20×10^{-4} c.c. per minute. This value varies somewhat with the age and chemical characteristics of the rubber.

5. The temperature coefficient of permeability is quite high. For example, in the tests at 100 deg. C. the permeability to carbon dioxide or helium was about seventeen times the rate at 0 deg. C.; the permeability to hydrogen was about twenty-two times as great at 100 deg. as at 0 deg. C.

6. The relative permeability of rubber to some common gases is shown in the following summary:

Gas	Relative Permeability Hydrogen = 1
Nitrogen.....	0.16
Air.....	0.22
Argon.....	0.26
Oxygen.....	0.45
Helium.....	0.65
Hydrogen.....	1.00
Carbon dioxide.....	2.9
Ammonia.....	8.0
Methyl chloride.....	18.5
Ethyl chloride.....	200.0

7. The permeability of rubber to water vapor is high—approximately fifty times the permeability to hydrogen. This value, not having been determined with any precision, is not included in the table above.

ACKNOWLEDGMENT

Special acknowledgment is due the Goodyear Tire & Rubber Co. for the samples of rubber and fabric furnished to us in the course of this work. Many of these were especially constructed to meet our specifications. The company's enthusiastic co-operation has been of great assistance.

Increasing Demand for Paints, Oils and Varnishes in South Manchuria

The erection of new buildings in connection with the development of South Manchuria should increase the importation of paints, oils, and varnishes, which have amounted to about \$1,000,000 annually, approximately 60 per cent of which was used by the South Manchurian Railway Co. Prior to the war, British and American paints dominated this market, but as it became more difficult to obtain the desired brands, because of the lack of shipping facilities, those of Japanese manufacture became better known. With the return of normal conditions the potentialities of this market have become greater, providing American makes can compete with the prevailing prices, as their superior quality is recognized. One of the brands now in demand is an ordinary lead paint, packed in drums of 28 and 112 lb., the former selling at \$2.50 and the latter at \$4.50. Mixed paints, put up in 1-lb. tins, sell wholesale at \$1.50 per dozen tins. Enamels, which are now in great demand, wholesale at \$3.50 per dozen tins of $\frac{1}{2}$ lb. each. Varnish is selling at \$4.20 per dozen tins of 2 lb. each. There are two kinds of paint oil on the market, one reported to be of pre-war stock is put up in 4-gal. drums, selling at \$7 per drum wholesale; and the other, a Japanese product, put up in 36-lb. drums, selling at \$4 per drum.

Synopsis of Recent Chemical & Metallurgical Literature

Slag Brick.—A. GÜTTMANN, in an article in *Stahl und Eisen* for March 4, describes Schol's process of making slag brick of high heat resistivity in use at the Oberseheld iron works. Here an iron furnace slag containing about 35 per cent SiO_2 and not less than 44 per cent CaO is pushed horizontally into a shallow pool, so as to be transformed into an almost frothy material called "thermosit," with a density of 0.3 and thermal conductivity of 0.07. The thermosit is screened and the grains of half an inch size and less are mixed with a certain proportion of a binding agent, prepared from fine slag sand and unslaked lime; the lime is slaked and the dried mixture is ground. One part of this slag-cement and six parts of the thermosit, together with water, are then introduced into a drum, from which they enter the brick press, in which pressure is applied first from the top and then from below. This mode of compression is adopted in order to obtain high porosity and high permeability as well as low thermal conductivity. The bricks leaving the press are very soft and have to be kept for about six hours in exhaust steam before being dried in the open air. In strength the bricks answer very well in houses of two or three stories, and do not soften under water.

Basic Open-hearth Slags.—At the 1920 meeting of the Iron and Steel Institute (British) JOHN F. WILSON presented some notes derived from his furnace experience on "Slag Conditions in Open-Hearth Basic Steel-Making Practice." Recognizing the fact that when melted, slag constituents are in solid solution with each other, he still was of the opinion that much information could be had from studying the acid: base ratio. Basic slags appear to adjust themselves to the furnace conditions, with the end of maintaining a viscosity not too thick or too thin—something like the consistency of cream. This criterion required somewhat different compositions for different temperatures; if, for instance, the slag is too thin, there must be added to it by the furnaceman sufficient ingredients to rectify the matter, or there will be reduced from the slag such elements as give increased fusibility (Fe, Mn, P), or, thirdly, chemical action will abstract from the tanks or metallic bath such elements as to make the slag less fusible. Correspondingly for slags too stiff.

Starting with that slag which is inert yet contains the highest proportion of acids possible in normal basic furnace work, the author notes that this slag has the desirable or creamy viscosity at the lowest temperature. This is called a "silicate slag." If, after allowing for lime-phosphorus and lime-sulphur compounds, the equivalent $\text{FeO} + \text{MnO} + \text{MgO}$ is more than $0.7 \times \text{CaO}$, the slag will be of the olivine type—purely monosilicates. If less than $0.7 \times \text{CaO}$ it is of the mellilite type with perhaps one molecule of bisilicates to two of monosilicate. If excess base is added to olivine slag, that excess quickly combines with acids from the metal to form silicates or phosphates. Excess silica from the metal reduces phosphorus or corrodes the tanks.

High-phosphate slags carry silicates of the olivine type, but are less fusible than silicate slags. Very high-

phosphorus slags are of economic importance, but in furnace work tend to carry excess base over the monosilicate requirement. This should be reduced to the minimum so as to keep the working temperature down and the soluble phosphorus up.

Tapping slags are best made up so that the steel is properly purified at a sufficiently high temperature, and by least expenditure of bases. Their constitution is quite complex, and must contain "active" bases in order to purify the metallic bath of S and P. Compounds between bases are probable.

Passing on to the effect of slag upon various furnace reactions, Mr. Wilson says that the principal methods of steel manufacture decrease in some way the depth of slag covering. Thick slag volume retards heat transmission into the metal bath, this requiring high flame temperatures and excessive wear on furnace. It blankets or smothers gas evolution from the steel, thereby slowing down the speed of decarbonization, and the intimate contact between metal and slag during the boil is hindered.

In the discussion, J. H. Whiteley said that one of the unexplained things about basic slags was the method by which iron oxide increased in analysis. It might be given off by the metal, but to only the slightest extent. Metallic globules in the slag might churn to the surface and become oxidized, but ordinarily shot iron in basic slags did not exceed 0.5 per cent, as compared to 5 per cent in the acid slag during the boil, in spite of which percentage iron oxide in the slag is then reduced. The only other possibility was the reaction $\text{Fe}_2\text{O}_3 + \text{Fe} = 3\text{FeO}$. While in the acid slag there might be 30 per cent of FeO in the slag as silicate and only 0.2 per cent of Fe_2O_3 , in the basic process there might be 8 per cent FeO and 2 per cent Fe_2O_3 . Possibly in basic slag the iron oxide was much less closely held in chemical combination and so was relatively free to become oxidized continually by furnace gases.

Silicon in Acid Steel.—A very clear discussion of the reaction occurring when silicon goes up just before tapping an acid heat was presented by B. YANESKE and G. A. WOOD, before the annual meeting of the British Iron and Steel Institute, in their paper entitled "Reduction of Silicon From the Slag in the Acid Open-Hearth Process." It is commonly known that sometimes a heat is tapped which eventually shows much more silicon than counted upon, although carbon and manganese are substantially correct. The authors have been able to study many such heats, following them back and constructing furnace logs, arriving at the conclusion that iron and not carbon is the reducing agent.

Close study shows the following occurrences for high-silicon heats: Silicon will increase continuously in metal if the bath is held quiet under a very siliceous slag; the action is accompanied by a loss in FeO analysis in the slag; yet silicon in the bath will be immediately reduced if either iron ore or lime be added, later to restart the cycle. Meanwhile carbon and manganese are substantially stationary, and may be anything from comparatively high to quite low. Dissolved oxygen in the metal is also very low, because actual losses of C, Mn and Cr during this period of the heat are less than would be expected. Temperature has no preponderating influence on the reduction of silicon and appears to act only indirectly by favoring a more acid slag.

The authors suggest a reaction (necessarily endothermic)

to explain all these facts, as well as the following: If tests be taken when the silicon first starts to be reduced, they will be pitted on the *under* side (liberation of gas from the slag which surrounds the entire metal in the spoon, but this gas is only imprisoned at the bottom). As the reaction in the furnace becomes stronger, tests are pitted both top and bottom, the holes being connected by badly oxidized channels (passage of oxygenated gas). Tests are pitted in upper surface exclusively, only where there is an excess of oxide in metal, by the reaction

Presence of oxide in metal during siliconization is impossible, as explained above, so tests pitted on the upper surface only are not found during the course of this phenomenon.

Campbell* advances the popularly held equation

Stoichiometric calculations show that nowhere near enough C is lost from a bath to correspond with its gain in Si. Even if ferrosilicon is melted on the banks, it will largely enter the metal ostensibly by oxidation, through the slag, and reduction, to the metal. Yet silicon can thus be added without lowering carbon an amount demanded by Campbell's equation. It is attractive because silicon is more easily reduced in a high-carbon melt; yet the authors quote figures from low-carbon heats showing siliconization from the slag. A slag over mild steel usually tends to increase in FeO and decrease in SiO₂ near the finish, and more oxygen is liable to enter the melt because of insufficient carbon being present to deoxidize. Siliconization ordinarily cannot be expected from a neutral slag overlying oxidized metal. The authors further state that at furnace temperatures silicon has a greater affinity for carbon than oxygen, so that Campbell's reaction is improbable, basing their argument upon their observations that carbon does not lower in high-silicon metal, until the silicon first is eliminated again, it is commonly known that a newly-sanded hearth produces a quiet boil and requires much more ore to oxidize carbon; in other words, the unusually high silicon then in the metal requires FeO to reduce it first, that done the carbon starts. The apparent inversion of affinities observed when running an acid bessemer very hot is explained thus: high temperatures require highly siliceous slag, which resupply silicon to the metal as fast as it is oxidized. On burning out the carbon to red fumes of iron oxide, the silicon is reduced simply because then enough FeO is produced to lower the acidity of the slag.

McCance† advances the equation

noting that an increase in temperature would lead to a greater reduction and the formation of more silicon. True, but it would also form more FeO, yet experience shows that the slag actually loses FeO during siliconization, and the action is initiated when FeO in slag is already very low. In fact oreing causes a loss in silicon in the metal. Nor does this reaction explain the holes in test pieces.

*"The Manufacture and Properties of Structural Steel." 1896 Edition. p. 110.

Recent Chemical & Metallurgical Patents

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

• **Synthetic Resins.**—Resinous condensation products are obtained by passing a vaporized mixture containing dienes such as isoprene, for example, the mixture of gases and vapors obtained by cracking mineral oil under high pressure, over a heated contact mass (bauxite, fuller's earth, clay, animal or vegetable charcoal, etc.) at a temperature above the melting point of the resin formed, say from 110 to 250 deg. C.; the molten resin is drawn off from the bottom of the contact vessel and solidified. The product is soluble in alcohol or ether, and may be used in the manufacture of varnishes, coating compositions, plastic compositions, insulating materials, etc., and may be vulcanized. (Br. Pat. 138,046—1919. HALL MOTOR FUEL, LTD., London, March 24, 1920.)

• **Catalysts for Ammonia.**—Catalysts for use in the synthesis of ammonia at atmospheric pressure and moderate temperatures and containing as the active constituent a metal which when heated in nitrogen forms a nitride decomposable by hydrogen are prepared by causing an oxide of such metal to react with a reducing metal such as aluminum or magnesium; the reaction mass which constitutes the catalyst contains the catalytic metal in a finely divided state and distributed over the oxide of the reducing metal, and by the use of such a catalyst the synthesis of ammonia is effected at a temperature lower than that necessary with the catalytic metal alone. The following are suitable catalytic metals—lithium, uranium, cerium, lanthanum, thorium, titanium, calcium, barium, strontium, glucinum, zirconium, vanadium and molybdenum; according to an example, finely powdered quicklime is intimately mixed with very finely powdered aluminum or magnesium, and reduction is started by igniting a length of magnesium ribbon introduced into the mixture. To obtain a greater dilution of the active metal in the catalyst, a further quantity of the reducing metal is added, and the reduction process repeated; and to regenerate the catalyst, fresh quantities of catalytic metal oxide and reducing metal are added, and the mixture brought to reaction as before. If the reaction mass is allowed to cool in the air or in pure nitrogen, the catalytic metal is in part converted into nitride, and the resulting catalyst is of increased activity. (Br. Pat. 140,061—1919. L. DUPARC and C. URFER, Geneva, May 12, 1920.)

• **Vulcanizing India Rubber.**—Natural or synthetic rubber is vulcanized by the addition of salts of mono- or di-substituted dithiocarbamic acids and di- or tri-valent metals or inorganic radicles, and sulphur, the amount of sulphur being reduced to 2 to 0.2 per cent of the rubber. In an example, a mixing of 100 parts rubber, 0.5 part sulphur, and 1 part pentamethylene dithiocarbonate of zinc, with or without the addition of mineral oxides, reclaimed rubber or substitutes, is vulcanized in the usual manner. (Br. Pat. 140,387—1919. G. BRUNI, Milan. See also 140,388—1919. May 12, 1920.)

Current Events

in the Chemical and Metallurgical Industries

New Jersey Clay Workers Meet at Trenton

The annual summer meeting of the New Jersey Clay Workers Association and Eastern Section of the American Ceramic Society was held at Trenton, N. J., June 25, with morning and afternoon sessions at the Trenton Country Club. This delightful spot proved an ideal location, and brought an inspiring environment to the gathering. About 65 members and guests were present from all parts of the state, as well as from New York and other neighboring sections.

HELPING THE NEW CERAMIC SCHOOL

The meeting was called to order shortly after 11 o'clock, opening with an interesting address by Chairman Abel Hansen, head of the Fords Porcelain Works, Perth Amboy, N. J. Mr. Hansen spoke of the new ceramic school at Rutgers' College, New Brunswick, made possible through the securing of an appropriation of \$100,000 from the state, during the last session of the legislature, and urged those present to help the movement with suitable donations of burned clay building materials, as well as general ceramic products. In this way, he pointed out, the fund will go even further than anticipated, making the new building a real monument to the State of New Jersey. He also brought out the need for interesting young men in the advantages of the institution, so that a representative class of students would be evidenced at all times. He said that the demand for ceramic engineers was great, and far in excess of the supply.

SAGGER MAKING

The technical session was inaugurated with a valuable paper by Charles F. Gieger of the Carborundum Co., on the subject of "Superior Saggings." This address traced the manufacture of saggings from the mixing of the clay to burning in the kiln, and pointed out some of the errors now prevalent in production, frequently making for saggings good for but one or two heats.

He said that choosing sagger mixtures on the basis of porosity, though a practice of long standing, was not to be recommended, because porosity is not the governing factor; the hot strength of the burned sagger mix and the rate of deterioration in strength on repeated heatings are items that should control the selection of a sagger mix. Most refractory materials, he set forth, have a much lower mechanical strength at temperatures above 1100 deg. C., than when cold, and in most instances, the primary cause is not due to the softening brought about through vitrification; it is simply that the physical properties are not the same at all temperatures.

The speaker explained preferred methods of preparing sagger mixes, covering the dry grinding of several clays together in a dry or wet pan, or in mills, followed by a thorough pugging in a wet pan, with mullers raised slightly. When the mix is thoroughly plastic, the grog is added, and the entire mass fully ground and mixed.

The concluding paper of the morning session was an interesting résumé on the subject of ceramic drying, covering some recent accomplishments in this line, presented by D. H. Applegate, Jr. of Proctor & Schwartz, Inc. The talk was illustrated with a number of lantern slides, showing various mechanical drying installations. Modern developments, it was pointed out, have made possible effective drying of ceramic wares in far less time than ever thought possible, and with a degree of accuracy and uniformity that leaves nothing to be desired.

STUDIES OF CLAY IN THE RAW STATE

Following a fine luncheon on the veranda of the club house, the afternoon meeting was opened with an illuminating address by A. V. Bleininger of the Bureau of Standards, on the subject of "Studies of Clay in the Raw State." The talk set forth data regarding investigations and experiments now being conducted by the Bureau, and which, it is expected, will terminate in a pronounced value to those in the ceramic industry.

These tests cover such matters as the influence of organic compounds on clay plasticity; the effect of salts in clay as utilized for paper manufacture; the rate of drying with regard to ultimate shrinkage; the introduction of chemicals to bring about desired colors in paper-making clay, and similar topics.

SELECTION OF REFRACTORIES

Mr. Bleininger's address was followed by an equally interesting and pertinent talk by R. M. Howe, Refractories Manufacturers' Association, Mellon Institute, on the topic of "The Selection of Refractories." This address was illustrated with a number of charts showing the results of tests conducted at the institute.

Mr. Howe mentioned facts relative to the mining and mixing of raw clay for the manufacture of firebrick and other high grade refractories. He spoke of the influence of grind on the finished article, making a comparison between finely ground and coarser grade materials. He dwelt at some length on the matter of spalling, and tests conducted along such lines, showing the defined relationship between the amount of grog used and the resistance to spalling.

FIRING WARES IN TUNNEL KILNS

The concluding paper of the meeting was one dealing with the subject of tunnel kilns by Conrad Dressler, American Dressler Tunnel Kilns, Inc., New York. The speaker traced the development of the modern tunnel kiln, and explained the degree of efficiency now obtained in burning spark plugs, electrical porcelain specialties and kindred products. Kilns of this character are being operated to cone 18 and 19, and giving highly satisfactory service.

A number of interesting pictures were thrown on the screen, setting forth various tunnel kiln installations in different parts of the country.

Hercules Powder Co. Sued by duPont Co. for Alleged Patent Infringement

A suit which is not only of interest as a legal battle between two great rival manufacturers of explosives and chemicals but also is of vital importance to practically every manufacturer of pyroxylin solutions, lacquers, artificial and split leathers, and celluloid articles, will soon be brought to trial in the federal district court for New Jersey.

The suit, based on alleged infringement of patents, has been instituted against the Hercules Powder Co. by the E. I. duPont de Nemours & Co. The patents upon which the action was brought, it is claimed by the duPont Co., protect the use of a mixture of ethyl acetate and benzol, with or without the addition of ethyl alcohol, as a solvent for nitro-cotton. As pyroxylin solutions, or dopes, used in the manufacture of split and artificial leathers, lacquers, cements, celluloid articles, and hundreds of other commodities, are frequently made by dissolving nitro-cotton in these solvents, and the two companies are among the leading competitors in the business, this suit assumes a high proportion of interest to many concerns throughout the country. Definitely stated, the patents which it is claimed have been infringed upon are numbers 1,118,498; 1,135,026; 1,321,633 and 1,321,634 granted to the duPont Co. as the assignee of Frederick Kniffen and M. V. Hitt. The two Kniffen patents specifically cover a solvent for pyroxylin consisting of ethyl acetate and benzol and the process of forming a body of pyroxylin made by dissolving pyroxylin in a mixture of ethyl acetate and benzol and then causing this mixture to evaporate. The two Hitt patents cover practically the same proposition, one claiming a solvent for pyroxylin and the other the use of this solvent to dissolve pyroxylin and consequently forming a body of it. The solvent covered is a mixture of ethyl acetate and benzol (or some higher member of the benzol series of hydrocarbons such as toluol), and ethyl alcohol, methyl alcohol, or some other volatile saturated aliphatic alcohol whose rate of evaporation is somewhat similar. This solvent is essentially the same as that involved in the Kniffen patent except that part of the ethyl acetate is displaced by alcohol. This is an alleged improvement on the Kniffen solvent.

It is understood that the Hercules Co. will try to show that the solvent, which is alleged to infringe on the duPont patents, was a matter of common knowledge years before the patents were taken out, and that the only reason ethyl acetate was not very generally employed was the availability and cheapness of other chemicals before it became a commercial commodity. With ethyl acetate on an available basis, it was, according to the belief of the Hercules Powder Co., put to an old and well recognized use in the solvent mixture about which the action has been brought.

Canadian Power Co. to Build Hydro-Electric Plant,

The Bridge River Power Co., Ltd., of Vancouver, B. C., is to develop hydro-electric power at the Bridge River power site. A total of 400,000 continuous hp. will be available when the site is fully developed and power in blocks of from 5,000 kw. up will be available within two years' time. Power will be sold as low as \$16 per hp. year, depending on whether the plant consuming the power is located at the power house or at a distance, also on the power and load factors.

The Gasoline Problem

In connection with the active and widespread efforts to find substitutes for gasoline Dr. Van H. Manning has expressed the opinion that the problem will be solved primarily by obtaining more gasoline from mineral matter. The following summing up of Dr. Manning's views was made in his capacity as Director of the Bureau of Mines, in fact just before he left the Government service to take charge of the research division of the American Petroleum Institute:

The present situation of high gasoline prices, and threatened shortage, has been caused by an increase in the uses of gasoline faster than the increase in production and importations of crude petroleum, from which it is derived. It is now found that sufficient gasoline cannot be obtained from the old processes of refining crude oils to meet the present and anticipated needs. Fortunately, however, processes have been developed in recent years for producing synthetic gasoline from the heavier and less volatile portions of the crude oils, from which processes some 15 per cent of the 4,000,000,000 gal. of gasoline produced in 1919 was derived. Synthetic gasoline can also be manufactured from oil shales and gasoline substitutes are being manufactured from byproduct coke ovens, and can be made by low-temperature destructive distillation of coals and lignites.

I am strongly of the opinion that the problem of obtaining greater supplies of gasoline will be solved primarily by obtaining supplies from mineral matter, and that alcohols and other substitutes derived from vegetable matter can be but a minor factor in the situation for an indeterminate period of time.

INCREASING THE YIELD OF PRESENT OIL FIELDS

Obviously, the most satisfactory solution of the problem would be to obtain greater supplies of crude oil, and for this reason our Government should give serious consideration to the encouragement of our nationals in acquiring supplies abroad. This Government should also do its utmost to provide technical and scientific guidance for the industry at home for the obtaining of more supplies of oil from our own fields. It is a fact not commonly known even in the oil industry, that the wells obtain but a small proportion of the oil which exists in the sands and that probably not more than from 10 to 20 per cent is commonly extracted. Oil is found in sands and sandstones in pores which are almost microscopic in size. When the gas which forces this oil out of the pores of the sands is exhausted, the remaining oil is held like water in a sponge and the well ceases to yield oil in commercial quantities although a larger part of the 80 to 90 per cent of the oil remaining can be obtained by the proper methods.

Some exceedingly promising methods have been in use for a number of years, which have proved indisputably that a great deal more oil can be obtained from our oil sands. But there are numerous important problems which will call for the best scientific and technical research for their solution before a full measure of our oil supplies can be obtained. I am strongly of the opinion that one of the first considerations in insuring a future supply of gasoline should be of this 80 to 90 per cent of the oil which is now being left in our fields, and that this Government should properly conduct the necessary technical and scientific investigations and foster the use of improved processes in every way possible.

Another problem which should receive immediate

consideration is the manufacture of synthetic gasoline from heavy oils. At the present time there is only one process which is being largely used—the so-called Burton cracking process held under patent by the Standard Oil Co. of Indiana. This process can use only one quality of oil, which is but a minor proportion of the heavier oils produced in this country. Some 40 to 50 per cent of all petroleum which is now being used in a most inefficient manner for steam raising would be made available for manufacture into synthetic gasoline by the development of a commercially practical process for cracking these heavy oils into synthetic gasoline. The discovery of such a process available to all refiners might readily double the quantity of gasoline obtainable from our present production of crude oil and defer any apprehension of a gasoline shortage for many years to come.

GASOLINE FROM OIL SHALES

In recent years, vast quantities of shales have been found in the Rocky Mountain states, in California, Kentucky, and many other states, from which can be obtained from half a barrel to over a barrel of oil per ton of shale. The U. S. Geological Survey estimates that the quantity of oil locked up in the shales of Colorado, Utah and Wyoming, is many times more than will ever be produced from our oil fields. From these shales, gasoline and other petroleum products may be obtained by retorting and refining. This has been a commercial process for over fifty years in Scotland. In fact, petroleum products were obtained in the United States from oil shales before the discovery of oil. Although there is considerable interest and experimentation going on looking to the utilization of these enormous supplies of petroleum products in the West, there are many problems to be solved before oils can be obtained successfully from shales. And to those who are endeavoring to develop this latent resource, there is need for the Government to render every service and encouragement in the way of research and otherwise, in order to hasten the date when oil from shales may be made available.

SUBSTITUTES FROM BYPRODUCT COKE OVENS

A considerable quantity of gasoline substitutes is now being obtained from byproduct coke ovens. It is expected that 95,000,000 gal. of benzol will be produced in 1920, which will be about 2 per cent of the total gasoline supplies for the year. Everything should be done to encourage and foster this industry. Still larger quantities of gasoline substitutes can be made by retorting the coal and lignites which now are being consumed as they come from the mines. If the available oil could be extracted from every ton of coal and lignite before they were consumed, it would add very greatly to the supplies of motor fuels. I wish to point out that the production of benzol from coals is likely to be inseparable from the utilization of alcohols from vegetable matter. It is a fact that the present gasoline-using engine cannot use straight alcohol satisfactorily; also, it is going to be practically necessary that any substitute for gasoline as an engine fuel must be practically interchangeable with gasoline. To accomplish this purpose it is necessary to blend alcohol with gasoline. But alcohol will not blend with gasoline unless there is a considerable quantity of benzol or a similar product in the mixture. Therefore, unless some other solution of this problem is found, it will be necessary to produce large

quantities of benzol from coal in order to blend the alcohol with gasoline and make it an interchangeable fuel.

ALCOHOL FROM VEGETABLE MATTER

At the present time but a comparatively small amount of alcohol produced from sugar refinery wastes is being placed on the market in competition with gasoline. This is being sold as alcohol, benzol, ether and gasoline blends. However, the quantity of alcohol obtainable from sugar refineries is negligible compared with our gasoline needs.

It is true that there are immense quantities of waste vegetable matter throughout the country, and were it possible to gather the refuse from the farms and from the lumber camps and other places, a tremendous quantity of alcohol could be obtained. But it is unfortunately true that this waste vegetable matter is widely scattered and in few places is it concentrated enough that it seems commercially feasible to make alcohol in competition with gasoline.

From a quantitative standpoint, petroleum, coal, and oil shale are likely to be the cheapest raw material for making gasoline substitutes. It must be borne in mind that the obtaining of gasoline substitutes alone will not solve the problems resulting from the failing petroleum supply. Gasoline is but one of the essential products from petroleum. An automobile, or farm tractor would be even more helpless without the lubricants obtained from petroleum than without the gasoline. There is not a moving part in any piece of machinery in the United States which does not take lubricants which are derived from petroleum.

SUGGESTED LINES OF INVESTIGATION

It would be a mistaken policy to limit the investigation of gasoline substitutes to vegetable matter. Emphasis should be placed on the investigation of the problems mentioned. Serious consideration should be given to encourage the development of gasoline and gasoline substitutes; (1) by increasing the recovery of oil from our oil fields, (2) by developing processes for making synthetic gasoline out of heavy oils, (3) by encouraging the development of processes for making gasoline and gasoline substitutes out of oil shales, coals, lignites, peats, and (4) by developing processes for making alcohols, ethers, etc., from waste vegetable matter.

Chemistry Co-operating in Plant Protection

Progress was achieved at the Rochester meeting on June 23 when a group of about thirty-five persons met under the auspices of the National Research Council and adopted tentatively articles of association for the proposed "Plant Protection Institute." This is one of the products of the vigorous effort by Dr. H. E. Howe, who is preaching the gospel of co-operative research and industrial development.

This movement includes entomologists, plant pathologists, and the makers of insecticides, fungicides, and the manufacturers of apparatus for the use of these materials. Agencies formally co-operating are the American Society of Economic Entomologists, the American Phytopathological Institute and manufacturers of equipment. It is hoped that standardized labels, standard directions for application of these materials and other similar co-operation can be achieved as well as the much needed research in the chemical and plant industry fields.

Swenson Evaporator Co. Wins Suit

The Swenson Evaporator Co. of Chicago, Ill., a company engaged in the manufacture of evaporators for various industries, sold to the Minneapolis & Ontario Paper Co. for its plant at International Falls, Minnesota, equipment amounting to \$170,000 in 1916. This material was delivered to the paper company so that the mill could be put in operation within less than a year.

Early in 1919, the evaporator company filed suit in the United States District Court at Minneapolis for the remaining amount due in accordance with contract, which was long overdue, claiming about \$40,000 and interest.

The paper company claimed that this money was not paid as the machinery was not built according to contract and filed a counter-claim for damages to the extent of \$700,000, this amount being gradually reduced by rulings of the court to \$92,000, as representing the maximum amount that could be due the defendant in case the jury decided they were entitled to any damages at all.

The trial opened on June 7, before Judge Booth of the United States District Court, in St. Paul, and lasted three weeks.

The paper company relied mainly upon the testimony of two former employees of the mill, Norman E. Brokaw and Prof. Adolph F. Myer.

The evaporator company's witnesses included Robert Woodhead, superintendent of the Canada Paper Co., C. F. Beyerl, who had charge of the construction of the mill in question and various employees and officers of the Swenson Evaporator Co.

The testimony proved, according to the verdict reached by the jury, that the troubles of the paper company were due to incompetent management and operation, and not to any faulty design or defects in material furnished. It was shown also that the machinery and plant were never given a fair trial, and that similar machinery made by the same company was giving satisfactory service at other pulp mills when operating on similar materials.

The case was submitted to the jury June 25, 1920, and a verdict for the Swenson Evaporator Co. for \$43,862 returned the next morning.

Chemical Merger Expected

Negotiations looking to the merger of several of the large byproduct and chemical companies are said to be progressing satisfactorily. The plan involves the merger of the General Chemical Co., Barrett Co., Semet-Solvay Co. and National Aniline Co. It is possible that an announcement bearing upon the proposed merger may be made before the close of the month. Prices at which the shares of certain of the subsidiary companies will go into the merger have been agreed upon.

It is understood that the aggregate earnings of the companies to be embodied in the merger—Barrett, National Aniline, General Chemical and Semet-Solvay—are now running at rate of \$30,000,000 annually of which National Aniline contributes about \$12,000,000.

Germany's Potash Industry

It is reported that the net profit of the German potash industry for the year 1919 was 7,661,511 marks, as compared to 2,317,667 marks for 1918.

Personal

COMFORT A. ADAMS, dean of Harvard School of Engineering, has resigned to devote his entire time to the work of the National Research Council, in which he is chairman of the Engineering Division.

Dr. EDWARD BARTOW, of Illinois University, has accepted a position as head of the chemical department for Iowa State University, Iowa City, Iowa.

FRED A. BIGELOW has been elected president of the Carpenter Steel Co., Reading, Pa., succeeding W. B. Kunhardt, who becomes chairman of the board of directors.

W. D. COLLINS has been designated as chief of the Quality-of-Water division of the United States Geological Survey. Mr. Collins formerly was a member of the chemical staff in the Water Resources laboratory of the Survey. For several years, however, he has been serving as a chemist in the Bureau of Chemistry, Department of Agriculture.

C. B. HOCKER, of the engineering department of the Western Electric Co., New York, is making an extended visit to the Chicago plant.

Prof. HECTOR JAMES HUGHES has been made dean of the Harvard University Engineering School, Cambridge, Mass., to succeed Comfort A. Adams, resigned.

Colonel ARTHUR B. LAMB, who is now in charge of the research laboratory of the Nitrate Division, at American University, Washington, D. C., has decided to resume his duties at Harvard University, and will return there in September.

J. B. MCINTOSH, well known among copper and lead men in the West, has resigned as superintendent of construction, Murray Plant, American Smelting and Refining Company, to accept the position of chief mechanical and construction engineer for Compañia de Real del Monte Pachuca, and will leave for Mexico July 15. Mr. McIntosh acted as civil engineer for the Anaconda Copper Mining Company for many years, having a prominent part in the construction of the Washoe Smelter. In 1907 and 1908 he acted as engineer in charge of construction for the Tooele Smelter, built by the same interests, resigning to go to Bisbee, Arizona, where he directed the preliminary work on the Clarksdale Smelter. For the past 8 or 10 years he has been attached to the engineering division of the Utah department, American Smelting and Refining Co. and has executed several notable improvements in their plants during that time.

HARRISON E. PATTEN has resigned from his position as physical chemist in the Bureau of Chemistry, Washington. He left his work there on the first of the present month.

W. N. PRITCHARD, Jr., formerly superintendent of a pulp mill of the Procter & Gamble Co., Augusta, Ga., is now doing research work on dyes for the Calco Chemical Co., Bound Brook, N. J.

GEORGE W. SARGENT has severed his connection with the Crucible Steel Co. of America as vice-president and metallurgist, and is now devoting his attention to the Molybdenum Corp. of America, of which he is president.

EARL STAFFORD has recently become a member of the engineering staff of Arthur D. Little, Inc., chemists and engineers, Cambridge, Mass. Mr. Stafford is a graduate of the Engineering School of Tufts College, 1908, and for the past twelve years has devoted his attention largely to hydro-electric developments with particular reference to ore treating plants, pulp and paper mills and light and power companies.

R. H. TAWNEY, who was a representative of labor on the so-called Sankey Commission investigating the English coal situation, spoke before the Chicago City Club on July 1 on the subject: "The Movement for the Nationalization of Mines in England."

ROBERT V. TOWNSEND, formerly chemist in charge of the chlorinated toluene products, Semet-Solvay Co., Syracuse,

N. Y., has accepted a position with the Victor Talking Machine Co., Camden, N. J., where he will organize and direct its department of chemical research.

Prof. ALFRED H. WHITE, head of the department of chemical engineering, University of Michigan, has sailed for France to be gone about a month in the interest of the Air Nitrates Corporation of New York City.

C. W. WRIGHT, of Rome, Italy, and his brother, C. A. Wright, formerly of the U. S. Bureau of Mines, sailed July 8 for Italy, on the S. S. Canopic. Their address will be 28 Via Parlamento, Rome.

Obituary

L. H. HASKELL, vice-president of the Southern Cotton Oil Co., died at his home in Savannah, Ga., on June 4, 1920.

B. F. MECHLING, director of Mechling Brothers, manufacturers of heavy chemicals, Camden, N. J., died on July 2, at his home in Philadelphia. He had been ill for the past two years but his condition was not serious until recently. In addition to his connection with Mechling Brothers he was president of the Albro-Clem Elevator Co. and the Elevator Safety Appliance Co., both of Philadelphia. Mr. Mechling was 73 years of age and is survived by his widow and three children.

Current Market Reports

The Non-Ferrous Metal Market

New York, July 9, 1920.—The outside market has advanced to 18.50c., as copper stocks dwindle. Spot lead practically does not exist. Zinc stocks, also, are very low.

	Cents per Lb.
Copper, electrolytic.....	19.00
Aluminum, 98 to 99 per cent.....	33.00

The Iron and Steel Market

Pittsburgh, July 9, 1920.

In the iron and steel industry production has increased and shipments have decreased, "Order No. 7" of the Interstate Commerce Commission being blamed for the latter and receiving no commendation for the former. It operates to decrease the supplies of open top cars for loading Connells-ville coke and for shipping pig iron and steel products, while the increased supplies of cars to coal mines have brought about a better distribution of coal, the byproduct coke ovens and steel mills being beneficiaries among others. What the iron and steel industry wants is to ship its accumulation of product, not means to produce still more and pile at a still greater rate.

JUNE PRODUCTION OF PIG IRON

Production of pig iron in June was at the rate of about 37,400,000 gross tons per annum. On the basis of estimating capacity under ordinarily favorable working conditions at 45,000,000 tons, rates of production have been approximately 90 per cent in March, 75 per cent in April, 79 per cent in May and 83 per cent in June. At the recent rate of increase October would see 100 per cent production. The March rate was the highest since October, 1918, the rail strikes coming in April, with a gradual recovery thereafter.

The report on steel ingot production in June is not yet available, but it seems fair to assume that ingot production has continued in relation to pig iron production, in which case the June rate of ingot production was about 43,200,000 gross tons per annum, capacity being somewhere between 50,000,000 and 55,000,000 tons, and probably nearer the higher figure. Normally the production of finished rolled steel is about 76 per cent of the ingot production, but at the present time the proportion is much less, as many mills are accumulating semi-finished steel, partly by reason of greater convenience in piling and partly because of uncertainty whether customers will want all steel that would now be rolled according to their specifications, at the late date at which some of the steel would be shipped, for even the point of shipping current production has not been reached, reduction of the accumulation being still farther in the future.

QUIET MARKETS

There is very little interest in the pig iron and steel markets, which are all very quiet, except for business between the Steel Corporation subsidiaries and their regular customers, which business has become of practically routine character, the customers having confidence in the Steel Corporation prices on account of their being lower than the prices named by any of the independents. Contracts and orders are placed even though the time of delivery is altogether uncertain. The matter of delivery is really a detail as the corporation is selling to customers who are now receiving steel, as far as shipping conditions permit, and it is merely a matter of extending the service, as time passes, for additional periods.

Little attempt is being made to prognosticate the future of the iron and steel markets, as everything is seen to hinge on transportation conditions, and the outlook in that respect is of course cloudy. Few observers doubt that transportation conditions really will improve very materially and long before winter, when indeed a fresh batch of troubles is likely to come. Three dates are to be mentioned as promising, directly or indirectly, some help in transportation by producing greater incentive to utilize to the best advantage the existing physical facilities: July 20, when the Railroad Labor Board is expected to make its awards; August 1, when the decision in the freight rate cases is expected; September 1, when the Government guarantee of railroad earnings expires and the railroads will have to earn whatever money they get.

LABOR OUTLOOK CLEAR

The Columbus convention reached an agreement in the matter of wage rates in sheet and tin mills hitherto controlled by the Amalgamated Association. The men receded

from their various strong demands, and some entirely minor concessions were made them. Several manufacturers who have hitherto been content to sign the Amalgamated Association scales year by year after the usual negotiations are now strongly disposed to discontinue this practice when a scale year terminates under conditions auspicious for such an undertaking. The workers' organization has controlled less than 40 per cent of the sheet and tin mills of the country, all the Steel Corporation mills, for instance, being open shop, and the organization has been largely in the nature of an employment agency, affording facilities for the manning of mills and their operation by dealing with a mill committee in the matter of petty grievances rather than with individuals. At some of the mills built in the past few years the scale has been signed from choice, on the belief that the plants could thus be gotten into operation more quickly. With the open shop such an important issue with the industry in general, such a disposition has disappeared.

Now that the American Federation of Labor has conceded to the Amalgamated Association jurisdiction in case of an effort to unionize the iron and steel industry as a whole, by promising the Amalgamated Association a 51 per cent vote on any organizing committee the federation may set up pursuant to the resolution at the recent Montreal convention, the common opinion in the iron and steel industry is that no general organizing effort will be made. In the circumstances there is not much incentive for the American Federation of Labor to undertake such an operation, while there is nothing in the recent history of the Amalgamated Association, in its narrow sphere, to attempt so large a proposition. The Amalgamated Association would not think of conducting such an organizing campaign as that of last year, with its very radical atmosphere, as the association is distinctly conservative, and yet as to producing results by way of a strike the methods pursued last year were easily the most likely to succeed, even if a strike based on agitation of such a character could not be expected to succeed.

The definite reason why the iron and steel industry has remained so readily on the open shop principle is that it has payment by results as to practically all its skilled labor, the remedy for labor unrest urged as the most effective in all recent councils on this subject, and the principle of payment by results is likely to be extended from time to time in the industry to reach men farther down than those now paid definitely on a tonnage basis.

The Chemical and Allied Industrial Markets

New York, July 9, 1920.

The chemical market is in the same erratic buying position that it has occupied recently. Offerings are few enough, at what buyers consider a fair price, and consequently there is little activity displayed. The transportation situation seems to be relieved somewhat and deliveries on contracts are being made more rapidly than they have for some time. The *potassium salts* have held firm throughout the period with some offerings of *caustic* being made at 30c. while other interests are holding out for 38@40c. per lb., but even at these figures there is very little material visible. *Bichromate of potash* is steady at 44c. on spot, with possible shading of few cents for future contract as producers are unable to take care of anything but contract business. Manufacturers have advanced the price of *potassium chlorate* to 16@17c. per lb., which represents a rise of 1c. per lb., caused by recent heavy demand. Current prices of *potassium bromide* are holding firm and 90c. is the average price with some interests going as high as 95c. per lb. *Copperas* has fallen off slightly to \$2.75@\$3 per cwt. against \$2.90@\$3 of the previous report caused by drop in the volume of business. It is impossible to locate *salt cake* for less than \$40 and as high as \$50 per ton is being quoted on material that has changed hands several times. A year ago \$8-\$10 per ton was a reasonable price. Offerings of *barium chloride* are being made at \$158@\$165 per ton and there is promise of the domestic market returning to normal in the face of importing competition. There has been little or no activity among the *acids* and previous quotations prevail.

Despite the predictions made earlier in the year that

there would be a sharp decline about July 1, the coal-tar products market maintains that inactive appearance that is becoming habitual, and from indications will continue to do so. It is thought by many that, if for no other reason than the Japanese money situation, this drop is bound to occur and has been merely deferred until the late fall. On the other hand, the more optimistic members believe that Japan is safely over the crisis and will be back in the market soon, which will have the effect of not only keeping prices firm but will also strengthen them. *Phenol* remains in good supply and Government resale material can be obtained at 12c. per lb. It was estimated that the 27,000,000 lb. placed on the open market, with conditional clauses against exportations and selling to jobbers, would last four years, based on the approximate consumption of 6,000,000 lb. per year, but there is some speculation rife as to whether this supply will hold out. However, the firm that is handling this material is certain that it will be available for at least a year or year and a half. There is no *naphthalene* being offered except in small lots and 19@21c. per lb. is being demanded. *Metaphenylenediamine* came up during the week and is quoted at \$1.23@\$1.30 per lb. against a low price of \$1.15 of the previous week. The supply of *aniline oil* and *salts* seems to be better and prices on these two items are easier at 32@38c. for the former and 40@45c. per lb. for the latter. *Beta-naphthol*, tech., is quoted at 88c. per lb. for spot material and 80@82c. on contract; the *sublimed* grade is nominally quoted at the same figures, but there is no material available. Producers of pure *benzol* have made an advance to 35@40½c. per gal., f.o.b. works, drums extra and returnable. *Toluol* and *solvent naphtha* were also advanced, the new quotations being 35@40c. per gal. for the former, and 30½@35½c. per gal. for the latter. These items forming the basis for most of the coal-tar products, there seems to be no indication of a weak and falling market.

WAXES

Paraffines hold the center of interest in this market. Scarcity combined with heavy demand is tending to hold prices at the present high levels. The different grades of this wax had range between 7@12½c. per lb., a year ago, against current range of 9@18½c., and it is thought that still higher levels will be reached. The flooding of the market with 2,000 tons of *carnauba*, No. 3, North country, has caused a drop in this item, which is now listed at 36@37c. per lb. against 43@44c. until the current quotation. *Japan wax* has been affected by the money conditions in the East and is considerably weaker at 19@19½c. per lb.

NAVAL STORES

This market is fast approaching last year's figures. In the case of the *rosins* it is already below that market which was quoted at \$15@\$16.95 for B-D grade, against \$12@\$15.95 current quotations. *Turpentine* a year ago was selling at \$1.10, and if present conditions prevail it will not be long before this limit is reached. Buyers are very few even at the present \$1.49 level, which is almost \$1 below the price asked three months ago.

MISCELLANEOUS

Molybdenum ore shows a marked increase in activity after a long interval of dullness. While the ore is now quoted at \$1 per lb. of MoS₃, an advance from 85c. business has been transacted at considerably below the dollar mark. The ore in most of these instances, however, represents odd lots and war-time stock purchased from munition works. The greater use of molybdenum for the making of parts in the automobile industry has done much to open up business.

In the *feldspar* market there has been an upward movement, with orders at least three months in advance of available stock. Little has been done toward working the Connecticut resources for the last six months and the Canadian mines show a similar inactivity. The ground product, f.o.b. New York State and North Carolina, is quoted at \$17 per net ton, a rise of \$1 within the week.

Connellsville coke is nominal at \$18@\$19, foundry, and \$17.50@\$18.50 furnace, with very little obtainable.

The Chicago Market

Chicago, Ill., July 8, 1920.

Quiet is the ruling spirit in local markets. On many items the difference between spot and future quotations is as high as 50 per cent, indicating that lower spot prices will arrive some time. This tends to discourage spot buying beyond certain and definite needs. A great portion of the capacity of producers is tied up under contract, which fact has driven the immediate and early delivery business into the hands of brokers and speculators. These interests, being affected by the general financial tightness, seem unable to hold prices in the face of weak demand and the general trend of the market is therefore downward.

Transportation conditions are improving. Last week an embargo was placed on intercity shipments in the Chicago District, embracing Hammond, Gary and similar nearby points. This was with a view to permitting the carriers to clear out the accumulation of through shipments, some of which have been stalled for weeks. Consumers depending for supplies on consignments from far-away points are being benefited thereby. Considerable worry as to the coal situation has been expressed, fears of a shortage during the coming winter being prevalent. A careful survey of the situation, however, indicates that there is no cause for alarm and production is keeping pace with demand, which is all that is ever expected this time of year.

HEAVY CHEMICALS

In general, spot market is weak, even in the face of very low supply and, as producers are well sold up for some time to come, but few transactions are recorded for future delivery. Shortage in *alkalis* is most pronounced, with prices changed but fractionally since last reported. *Caustic soda* has been all but unobtainable, the prices mentioned being 6½c. per pound on the solid and 6c. on the granulated. These quotations should be considered as nominal. *Salt soda* shows increasing strength with contract business going, at \$1.70@ \$1.75 per cwt., spots running up to \$1.90, and goods hard to locate at any figure. *Bleach* and *soda ash* show no change.

Producers of *alcohol* remain wholly unable to keep up with demand, the scarcity of the *methyl* grade being most pronounced. Not only are manufacturers having difficulty in securing molasses but the supply they do get is weaker in sugar content than that formerly obtained, owing to a greater effort by the sugar refiner to extract all the sugar possible. This is caused by the present abnormal price on sugar, and the apparent impending break in this commodity may relieve the condition. Meanwhile, the conversion of molasses plants to corn continues. *Denatured alcohol*, normally around 50c. at this time of the year, is firm at \$1.09 per gal., owing to its wide consumption by industries ordinarily using *methyl*. *Methyl*, when found, is going at \$3.65 per gal. for 95 per cent and considerable contract business is being closed both at that figure and on an open price basis. Market on *ethyl* grade is unchanged. *Formaldehyde*, still hampered by alcohol shortage, remains scarce with price firm at 55c.

Mercury remains firm at a price of \$90 per flask, which is notable in view of the fact that various mercurial products which are factors in the drug trade were reduced by the manufacturers. *Aqua ammonia*, on contracts, remains unchanged, but practically all spots are second hand, on which definite quotations are unavailable. Transactions in carboys ranged up as high as 15c. per pound for 26 deg. Demand for *sal ammoniac* is off and price has dropped on the lump variety to 23@24c. per lb. and on the refined gray to 16c. Domestic *barium chloride* is hard to get. The imported is quoted at \$175 a ton, nominally, as local supply is about exhausted. *Carbon tetrachloride* is weak on spots, 11c. being the high figure on recent transactions. Contracts cannot be negotiated at much below 13c.

Nothing of interest has occurred in the acid trade in the past fortnight other than a reduction in producers' quotation on *pyrogallol*. Makers now offer the re-sublimed at \$2.35@ \$2.40 per lb. and the crystals at 40c. less.

COAL-TAR PRODUCTS

The great shortage in all classes of coal-tar products still maintains although reduced activities in the textile industry

should cause a lessened call for colors. Inquiry remains light, in the face of which advances were registered July 1 on *naphtha*, *benzol* and *toluol*. Pure *benzol* is now quoted at 35c. per gal., *naphtha* at 30c. and *toluol* at 35c. As producers are far behind on contracts and but few transactions are recorded in spots, these prices are almost nominal. Ordinary routine transactions in the acids have left prices unchanged.

Formerly noted uncertainty in price on *aniline salt* has ended with the price firm at 38c. per lb. The same is true of *aniline oil*, 33½c. being current. The advance in *benzol* indicates no further depression on these items. Spot stocks of *naphthalene* are practically exhausted and quotations depend on the buyers' need for supplies. Fluctuation is so great as to render a report useless.

VEGETABLE OILS

Buyers' apathy continues. Favorable growing weather for cotton coupled with an optimistic government crop report served to discourage *cottonseed oil* buying and nothing has occurred to stimulate the demand on any other item in the line. *Linseed oil*, suffering from the public's refusal to buy on a declining market, is moving slowly, but the price is firm at from \$1.54 per gal. in tank cars to \$1.64 in barrels f.o.b. warehouse. All other oils in this market show but fractional changes.

NAVAL STORES

Turpentine on local sales has declined abruptly from a figure of \$2.20 a gal. two weeks ago; it is now down to \$1.75 to \$1.85, with buyers showing no eagerness to load up. No great business is to be anticipated until prices demonstrate stability. Transportation conditions are considerably improved so that immediate requirements are being filled with little trouble.

Pine oil, both pure and destructively distilled, remains very hard to get, and is unchanged in price.

The St. Louis Market

St. Louis, Mo., July 6, 1920.

There has been little change in the chemical market during the past two weeks and prices for the most part have remained stationary. Local stocks are low, especially of chemicals which are not produced locally. The railroad situation has not improved materially and carload shipments are slow and deliveries erratic.

HEAVY CHEMICALS

Local producers report little spot buying but many inquiries by contract buyers. The market for *sulphuric acid* is quiet and prices unchanged. The 60 deg. grade is quoted in carload lots at \$15 to \$16 per ton and 66 deg. grade at \$22 per ton. The demand for *oleum* continues light and price is unchanged at \$27.50 per ton. There has been little change in the demand for *muratic acid* and the price remains at \$25 per ton in carload lots and 2@2½c. per pound in carboys for the 18 degree grade. The supply of *sodium bisulphate* is very short and the demand good. Quotation remains unchanged at \$6 per ton in carload lots.

The market for *nitric acid* is quiet and prices unchanged. The 36 deg. grade is quoted at \$7 per cwt., 38 deg. grade at \$8, 40 deg. grade at \$9 and the 42 deg. grade at \$10, in carload lots. The recent action of the Chilean association of producers in advancing the prices of *nitrate of soda* will undoubtedly cause an increase of price of *nitric acid*, as soon as the new supplies reach the market.

Quotations on *phenol* are unchanged at 12c. per lb. in quantities 15 tons and over. The supply is plentiful, due to a local firm disposing of surplus Government stock. The supply of *zinc oxide* is very limited and manufacturers are quoting on third quarter delivery. Prices are firm at 9@10½c. per lb., depending on the grade.

There is a fair demand for *caustic soda* and supplies are more plentiful. Prices are unchanged at \$6.25 per lb. in carload lots. *Soda ash* is unchanged at \$3.75 per lb.

The supplies of all grades of *alcohol* are very limited and the demand light. *Denatured alcohol* in Nos. 4 and 5 grades is quoted at \$1.06 per gal.

Resorcin, pure.....lb.	6.25 - 6.75	6.25 - 6.75

Sulfolie acid, tech., in bbls. (110 lb.)	lb.	\$0.50	—	\$0.52
Sulfolie acid, U. S. P.	lb.	.50	—	.60
Solol.	lb.	.90	—	1.00
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.33	—	.35
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.42	—	.26
Sulphanilic acid, crude	lb.	.32	—	.35
Toluidine	lb.	1.70	—	2.50
Toluidine, mixed	lb.	.45	—	.55
Toluol, in tank cars	gal.	.35	—	.35
Toluol, in drums	gal.	.38	—	.40
Xylidine, drums, 100 gal.	lb.	.50	—	.65
Xylol, pure, in drums	gal.	.37	—	.45
Xylol, pure, in tank cars	gal.	.35	—	.35
Xylol, commercial, in drums, 100 gal.	gal.	.37	—	.45
Xylol, commercial, in tank cars	gal.	.23	—	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark	lb.	\$0.36	—	\$0.39
Beeswax, refined, light	lb.	.39	—	.40
Beeswax, white pure	lb.	.63	—	.68
Carnauba, No. 1 (nominal)	lb.	1.00	—	1.05
Carnauba, No. 2, regular (nominal)	lb.	.85	—	.88
Carnauba, No. 3, North Country	lb.	.36	—	.37
Japan	lb.	.19	—	.19
Montan, crude	lb.	.23	—	.25
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.09	—	.09
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.09	—	.10
Paraffine waxes, refined, 118-120 m.p.	lb.	.11	—	.12
Paraffine waxes, refined, 128-130 m.p.	lb.	.14	—	.15
Paraffine waxes, refined, 133-135 m.p.	lb.	.16	—	.17
Paraffine waxes, refined, 135-137 m.p.	lb.	.17	—	.18
Stearic acid, single pressed	lb.	.25	—	.26
Stearic acid, double pressed	lb.	.26	—	.27
Stearic acid, triple pressed	lb.	.27	—	.28

NOTE: Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.				
Pine oil, steam dist., sp. gr. 0.930-0.940	gal.	\$1.80	—	
Pine oil, pure, dest. dist.	gal.	1.60	—	
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.48	—	
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.35	—	
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.	.85	—	
Pine tar, ref., thin, sp. gr. 1.080-1.060	gal.	.36	—	
Turpentine, crude, sp. gr. 0.900-0.970	gal.	1.75	—	
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990	gal.	.35	—	
Pinewood creosote, ref.	gal.	.52	—	

Naval Stores

The following prices are f.o.b. New York, for carload lots.

Rosin H-D, bbl.	280 lb.	\$12.00	—	\$15.05
Rosin E-I	280 lb.	15.95	—	16.10
Rosin K-N	280 lb.	16.10	—	16.20

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arizona

DUNCAN—Joseph Hardy plans to build a 100-ton cyanide mill at its gold mine here.

District of Columbia

WASHINGTON—The Bureau of Yards & Docks, Navy Dept., has awarded the contract for the construction of certain alterations and additions to the Aeronautical Engine Testing Laboratory Building at the Navy Yard here, to Hyde & Baxter, 711 13th St., N. W., at \$14,990. Noted July 8.

Illinois

NEWTON—The city plans to extend the present waterworks system, including a filter plant. Estimated cost, \$25,000. Fuller & Beard, Chemical Bldg., St. Louis, Mo., engr.

Kansas

GREAT BEND—The Sisters of St. Dominic have awarded the general contract for the construction of a 3-story, 50x150-ft. hospital, to T. C. Cork. A chemical laboratory will be installed in same. Estimated cost, \$150,000.

Kentucky

HENDERSON—The Lucking Distributing Co., Cincinnati, O., has purchased the plant of the Peerless Distilling Co., here, and plans to make improvements and install machinery in same, for the manufacture of grain alcohol. Estimated cost, \$30,000.

LOUISVILLE—The Dixie Belle Refining Co., 701 Inter-Saw Bldg., plans to build a refinery on Western Parkway.

LOUISVILLE—The Stall Oil Refining Co., 733 River Rd., is in the market for lubricating machinery.

Maryland

ST. HELENA—The Glidden Co., Madison Ave., N. W., Cleveland, O., has purchased the lithopone plant of the Chemical Pigments Corp., here, and plans to increase the capacity of same.

Massachusetts

CAMBRIDGE—The Presto-Lite Co., Inc., 30 East 42nd St., New York City, will receive bids until August 5 for the construction of a 1-story, 25x100-ft., acetylene plant, here. Estimated cost, \$80,000. Noted April 14.

SPRINGFIELD—The Westinghouse Electric & Mfg. Co., Page Bldg., has awarded the contract for the construction of a 1-story, 125x160-ft. foundry, to Bernard H. Prack, Keystone Bldg., Pittsburgh, Pa. Estimated cost, \$85,000.

Michigan

DETROIT—The Michigan Grey Iron Castings Co., Harbaugh Ave. and Wabash Ry., is in the market for miscellaneous foundry equipment for plant addition.

GRAND RAPIDS—The Amer. Can Co., 130 B'way, New York City, will soon award the contract for the construction of a factory on 6th St. Estimated cost, \$1,000,000. M. M. Loony, 120 B'way, New York City, archt. and engr.

Minnesota

FREEPORT—The city engaged the Bradley Eng. Co., engr., St. Cloud, to prepare plans for a sewage system, including imhoff tanks and sludge beds. Estimated cost, \$30,000.

Missouri

MOBERLY—The city plans an election to vote on \$250,000 bonds to construct a pumping and filtration plant, etc.

New Jersey

IRVINGTON—The Atlas Foundry Co. plans to construct a 60x60-ft. grey iron foundry addition, and is in the market for machinery for, same. Estimated cost, \$8,000. W. E. Lehman, Newark, engr. W. H. Mantz, genl. mgr.

New York

ALBANY—H. M. Biggs, State Comr. of the Health Dept. Laboratory, will soon receive bids for the construction of a 1-story, 31x85-ft. laboratory building. Estimated cost, \$15,000.

BROOKLYN—The Natl. Lead Co., 111 B'way, New York City, has awarded the contract for the construction of a 4-story, 50x100-ft. factory on Marshall St., to the White Constr. Co., 95 Madison Ave., New York City, at \$110,000.

BUFFALO—The F. F. Dally Co. of New York, 227 Military Rd., plans to construct a 1-story, 28x127-ft., addition to plant for the manufacture of blacking. Estimated cost, \$6,000.

BUFFALO—The Linde Air Products Co., 1681 Fillmore Ave., plans to repair laboratory building recently destroyed by fire. Estimated cost, \$4,000.

BUFFALO—The North Buffalo Hardware Fdry. Co., 743 Hertel Ave., plans to alter a 1-story, 67x350-ft., foundry. Estimated cost, \$6,000.

BUFFALO—The University of Buffalo, 24 High St., is having plans prepared for a 3-story chemical laboratory. Estimated cost, about \$300,000. McKim Mead & White, 101 Park Ave., New York City, archts. and engr.

NEW YORK—Sommerfeld & Steckler, archts. and engr., 31 Union Sq., will receive bids about August 2 for the construction of a 7-story, 50x50-ft. factory for the Rigaud Perfume Co., 75 Barron St.

Ohio

AKRON—The Goodrich Co., South Main St., plans to build several buildings, including a water-softening plant, etc., on Rubber and Falor Sts. Estimated cost, \$10,000,000.

CANTON—The city plans to construct a sewage disposal plant 10 miles south of here. Imhoff tanks will be installed in same. W. E. Sarver, city engr.

CANTON—The Timken Roller Bearing Co., Dufer Ave., will build a 1-story, 120x200-ft. factory addition to its tube mill for the manufacture of steel on Harrison Ave., S. W. Estimated cost, \$40,000. Work will be done by day labor.

CINCINNATI—The Amer. Can Co., 120 B'way, New York City, has awarded the contract for the construction of a can factory, including a 6-story, 72x260-ft.; 1-story, 60x1400 ft.; 1-story, 90x97-ft., and a 1-story, 80x160-ft., buildings, to the Ferro Concrete Constr. Co., Richmond and Harriet Sts. Estimated cost, \$1,000,000. Noted April 14.

CLEVELAND—The city has awarded the contract for the construction of a filtration plant at the Baldwin Reservoir to R. E. Carey Co., West 112th St. Estimated cost, \$312,360. Noted May 12.

CLEVELAND—The General Chemical Co., Warner Rd., S. E., has awarded the contract for the construction of a large addition to the national works of the company, including a sulphate of alumina plant, to the J. G. White Eng. Corp., 43 Exchange Pl., New York City.

CLEVELAND—The Hydraulic Pressed Steel Co., Hydraulic Ave., has awarded the contract for the construction of a 1-story, 75x200-ft., factory addition at 5764 Hydraulic Ave., to Craig Curtis Co., 1031 Guardian Bldg. Estimated cost, \$75,000.

CLEVELAND—The Lake Erie Steel Co., Stop 13 A.B.C. line, has awarded the contract for the construction of a 1-story, 50x150-ft., steel mill addition, to the Republic Structural Iron Wks. Co., East 53rd St. Estimated cost, \$75,000.

CLEVELAND—The Mechanical Rubber Co., Liebon Rd., has awarded the contract for the construction of a 1-story, 84x108-ft., substation, to the Stone & Webster Co., Leader-News Bldg. Estimated cost, \$100,000.

CLEVELAND—The Union Rolling Mills Co., 8200 Aetna Rd., had plans prepared for the construction of a 1-story, 42x182-ft. rolling mill addition. Estimated cost, \$30,000. William Davis, 593 The Arcade, archt. and engr.

CLEVELAND—D. D. Wessels, 1385 East 173rd St., is having plans prepared for the construction of a 2-story, 100x110-ft., factory for the manufacture of concrete tubs, on East 21st St. and Oregon Ave. Estimated cost, \$100,000. W. G. Caldwell, Park Bldg., archt.

COLUMBUS—The Atlas Brass Fdry. Co., 980 South Park St., has awarded the contract for the construction of a 1-story, 80x100-ft., brass foundry on Stewart Ave., to Nonnemachee & Frank, 427 Citizen Bank Bldg. Estimated cost, \$20,000.

LORAIN—The West Shore Realty Co., care Holland Eng. Co., E. of L. E. Bldg., Cleveland, will soon award the contract for the construction of a sewer, water main and sewage disposal plant with two septic tanks. Estimated cost, \$35,000.

OXFORD—The Miami University plans to build 3 buildings, including an addition to the Chemistry Building. Chemical equipment will be installed in same. Estimated cost, \$125,000.

TROY—The Gummed Products Co. plans to construct a 2-story, 100x140-ft. factory on Market St. Estimated cost, \$200,000.

Oklahoma

KEELYVILLE—J. W. St. Sing, clerk of the Bd. Educ., plans to build a 2-story high school here. A chemical laboratory will be installed in same. Estimated cost, \$50,000.

OKLAHOMA CITY—The city is having preliminary plans prepared for the construction of a sewage disposal plant, etc. Estimated cost, \$1,000,000. Fuller & McClintock, 170 B'way, New York City, engr.

PERRY—The city is having preliminary plans prepared for the construction of a sewage disposal plant here. Black & Vench, 701 Mutual Bldg., Kansas City, Mo., consult. engr.

Pennsylvania

JEANNETTE—The Amer. Window Glass Co., Farmers' Bank Bldg., Pittsburgh, has awarded the contract for the construction of a 1-story, 42x180-ft., cutting-room building, to the Bollinger-Andrews Co., Empire Bldg., Pittsburgh. Noted May 12.

PHILADELPHIA—John N. Gill Co., Otis Bldg., is constructing a factory to be used as a machine shop and erection shop for vacuum dryers and chemical machinery, on a 5-acre site near Cedar Grove Station on the Frankford Branch of the Philadelphia and Reading R.R.

PHILADELPHIA—The Prest-O-Lite Co., Inc., 30 East 42nd St., New York City, will receive bids until August 5 for the construction of a 1-story, 25x100-ft., acetylene plant, here. Estimated cost, \$80,000. Noted April 7.

South Dakota

DE SMET—The Bd. Educ. is having plans prepared for the construction of a 2-story, 60x133-ft., high school. A chemical laboratory will be installed in same. Estimated cost, \$100,000. W. L. Alban, Endicott Bldg., St. Paul, Minn., archt.

Vermont

PROCTOR—The Vermont Marble Co. is building a marble sawing mill.

Virginia

RICHMOND—The Amer. Lace Leather Co., Virginia St., between 13th and 14th Sts., is having plans prepared for the construction of a building. Carneal & Johnson, Chamber of Commerce Bldg., archts.

RICHMOND—The Virginia-Carolina Chemical Co., 12th St., had plans prepared for the construction of a 5-story steel factory. Estimated cost, \$250,000.

West Virginia

CHATTAROY—The Bd. Educ. plans to build a high school here. A chemical laboratory will be installed in same. Estimated cost, \$100,000.

MARTINSBURG—The Natl. Shale Brick Co. plans to construct a brick plant. Estimated cost, \$250,000.

WARWOOD—The Wheeling Cement Products & Building Co., 622 Wheeling

Bank & Trust Co. Bldg., Wheeling, will build a plant for the manufacture of building tile here. Estimated cost, \$35,000. Work will be done by day labor.

Wisconsin

CUMBERLAND—The city is having plans prepared for the construction of a sanitary sewer system and treatment plant. Estimated cost, \$50,000. L. P. Wolff, Guardian Life Bldg., St. Paul, Minn., engr.

RACINE—The Hamilton Beach Mfg. Co., Rapids Drive, is having plans prepared for the construction of a 1-story, 80x200-ft. foundry. Foundry equipment will be installed in same. Estimated cost, \$60,000. A. L. Tegel, Baker Block, archt.

WAUKESHA—The Waukesha Casting Co., 340 B'way, is having plans prepared for the construction of a 1-story, 120x130-ft. foundry. Estimated cost, \$50,000. C. Kavin Co., 431 South Dearborn St., Chicago, engr.

Quebec

CHILSEA—The Royal Securities Co., 164th and St. James Sts., will receive bids in August for the construction of a pulp and paper plant here. Noted April 21.

MONTREAL—The Pottery Co., Ltd., has purchased a large site in the eastern section of the city and plans to construct a plant on same. The company is in the market for additional kilns.

Ontario

LONDON—The Bd. Educ., 848 Dufferin Ave., will receive bids until August 1 for the construction of a collegiate building on Waterloo St. Physics and chemistry laboratory equipment will be installed in same. Estimated cost, \$500,000. L. V. Carrothers, Hydro Bldg., archt.

WINDSOR—C. W. Ripley, 519 Sandwich St., plans to build a foundry on Sandwich St. Estimated cost, \$25,000.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its 1920 meeting Dec. 27, 1920, to Jan. 1, 1921, at Chicago, Illinois.

AMERICAN CERAMIC SOCIETY will hold its summer meeting at the La Salle Hotel in Chicago, Aug. 16, 17 and 18.

AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Chicago, Sept. 7 to 10 inclusive.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in the Hotel Statler, Cleveland, Ohio, Sept. 30, Oct. 1 and 2.

AMERICAN FOUNDRYMEN'S ASSOCIATION will meet in Columbus, Ohio, Oct. 4 to 8 inclusive.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its one hundred and twenty-second meeting Aug. 20 to Sept. 3, at Lake Superior.

AMERICAN MINING CONGRESS will hold its next convention in Denver Nov. 15.

AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

AMERICAN STEEL TREATERS' SOCIETY, Chicago, will hold its second annual convention and exhibit, combined with the convention of the Steel Treating Research Society of Detroit, Mich., in the Coliseum Museum, Philadelphia, Pa., Sept. 14 to 18 inclusive.

ASSOCIATION OF IRON AND STEEL ELECTRICAL ENGINEERS will hold its 14th annual convention at the Hotel Pennsylvania, New York City, Sept. 20 to 24, 1920.

ENGINEERING COUNCIL will hold its next meeting in Chicago, Thursday, Oct. 21, 1920.

FOREST PRODUCTS LABORATORY will hold its decennial celebration at Madison, Wis., July 22 and 23, 1920.

INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

INSECTICIDE AND DISINFECTANT MANUFACTURERS' ASSOCIATION will hold its midsummer meeting at Boston, July 15 and 16.

IRON AND STEEL INSTITUTE (British) will hold its autumn meeting at Cardiff by invitation of the Ironmasters and Steel Manufacturers of South Wales and Monmouthshire. The date of the meeting will be Tuesday, Sept. 21, for the assembling of the members at Cardiff, and the formal proceedings will open on the morning of Wednesday, Sept. 22.

POSITION OF CHEMICAL INDUSTRIES (SIXTH) will be held in the Grand Central Palace, New York City, Sept. 20 to 25.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall national convention at Carnegie Music Hall, Pittsburgh, Pa., Nov. 10, 11 and 12, 1920.

TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its fall meeting at Saratoga Springs, N. Y., Sept. 1, 2 and 3.

Industrial Notes

PARSONS, KLAPP, BRINCKERHOFF and DORGLAS announce the removal of their general and engineering offices from 60 Wall St. to their own building at 84 Pine St., New York.

THE GENERAL FIRE PROOF CO., Youngstown, Ohio, devotes its May issue of "General Fire Proofing" to the problem of industrial housing and contains examples of recent projects.

THE STOKER MANUFACTURERS ASSOCIATION recently held a meeting at Lakewood, N. J., at which the following officers and executive committee were elected: Sanford Riley, president; M. Alpern, vice-president; A. G. Pratt, treasurer; S. A. Armstrong and H. A. Hutton, on the committee, and J. G. Worker, secretary.

HARRY LEVEY, Inc., has been organized as the first motion picture producing company which will devote itself exclusively to the making of industrial and educational motion pictures. Arrangements have already been made for the production of a series of pictures showing the making of dyes, explosives, automobiles, airplanes, paints, leather and electrical apparatus. Temporary offices are at the Hotel Astor, New York. Production studios are at 109 East 124th St., New York.

THE INTER-RACIAL COUNCIL, Woolworth Building, New York City, has established an information service for the benefit of employers of foreign born labor and for the workers themselves. The object of the service is to stabilize immigrant labor and to promote better relations between the various races in America and native born. The service will also check the tendency of the foreign born to return to their native land under the mistaken impression that prices are lower and living conditions better than in America.

THE GENERAL BRIQUETTING CO., New York, announces the appointment of Thomas F. Kelly, formerly with the Lackawanna Steel Co., as sales engineer of the fine dust, ore and by-products department.

THE CRESCENT BELT FASTENER CO., New York, has recently published a booklet on "Modern Scientific Methods of Belt Joining" which contains many practical data to those interested in the maintenance of production schedules and continuous performance of machines where belting is used. Instructions are given which will enable anyone to make belt joints, retaining the belt's full strength and assuring long life. Essential data are presented on a single sheet which can be suitably displayed on the wall. Copies of this illustrated circular will be sent upon request.

W. J. RAINY, Inc. is the name of the new incorporation of the business heretofore carried on under the name of W. J. Rainey, as announced by the Trustees of the Estate of W. J. Rainey. The officers of the new corporation are: Roy A. Rainey, chairman of the board, Scott Stewart, president and treasurer; L. L. Willard, vice-president in charge of operations; John McElwain, vice-president in charge of

sales and purchases of raw materials; H. R. Ahrens, secretary. The executive offices of the company will remain at 52 Vanderbilt Ave., New York.

THE CHICAGO PNEUMATIC TOOL CO., New York, announces the election of Allan E. Goodhue as vice-president in charge of sales. Mr. Goodhue since May 1, 1918, has been managing director of the company's English subsidiary, The Consolidated Pneumatic Tool Co., London, England; also director of European sales for the Chicago Pneumatic Tool Co. He sails for New York on the "Olympic" and is scheduled to arrive about July 3.

SKF INDUSTRIES, Inc., at a special meeting held May 13, 1920, accepted the resignation of B. G. Prytz, as president. Mr. Prytz has been elected managing director of the parent company, with headquarters at Gothenburg, Sweden. At the same meeting F. B. Kirkbride, vice-president since the organization of the company, was elected president.

THE ELECTRIC FURNACE CONSTRUCTION CO., Philadelphia, Pa., reports an order for a 1-ton "Greaves-Etchells" furnace for the Buenos Ayres Western Ry. Ltd.

THE WICKWIRE SPENCER STEEL CORP., Buffalo, N. Y., which publishes "Wick-Tack" has issued a very interesting number for June, 1920, which contains items on the personnel of the company, association activities, articles and editorials.

J. G. WHITE ENGINEERING CORP. announces that they have received a commission to build a very large addition to the National Works of the General Chemical Co. at Cleveland, Ohio. One of the most important features of the addition will be a sulphate of aluminum plant of large capacity. The engineers have been working on the engineering plans for some months and it is expected that the construction work will be started at an early date.

FRANK L. MCCARTNEY, formerly New York branch manager for the Monsanto Chemical Co., has been appointed general sales manager, with complete charge of all sales for all plants, including branch houses.

JOB. RISEMAN & Co., 152 Broadway, N. Y., announce that their business will be carried on from the new address given herewith.

BLAW-KNOX Co. announce that "Blaw-Knox" is the new name conferred by the United States Senate upon the town of Hoboken, Pa., the home of the company. The company first established in Hoboken about five years ago, occupying a comparatively small shop, at the same time operating another plant at Wheatland, Pa. About two years ago the latter plant was removed and added to the Hoboken works. The magnitude of the works has since increased by the erection of a large hammer-welding plant, augmenting the already extensive oxy-acetylene and electric welding facilities of Blaw-Knox Company. About 1,000 persons are employed in the shops, most of whom live in Old Hoboken. A petition signed by the people of the town, asking the Senate to change the postoffice name to Blawnox, has just been granted. This company also announces that Dewitt Clinton Grove, past vice-president of the Technical Publicity Association, has become advertising manager of the company. He succeeds George Land, who resigned July 1, to enter the agency field as head of the Technical Publicity Co. of Pittsburgh.

THE SWENSON EVAPORATOR CO. of Chicago is selling a large evaporator for export to Chile to be used in research for the production of Chilean nitrate.

THE DETROIT ENGINEERING SOCIETY entertained a Swiss delegation of sixty-five members in Detroit recently. The party made a thorough inspection of industrial plants in and about Detroit.

ARTHUR R. MAAS LABORATORIES, Los Angeles, Cal., has issued a twenty-two page pamphlet entitled "Chemistry and You," which has been issued for the purpose of acquainting those interested with their business, Chemical Service. The laboratories are equipped to handle problems related to industrial developments on the Pacific Coast, "from test tube to factory," having a well equipped laboratory and the necessary apparatus to test out processes on a semi-commercial scale. Arthur R. Maas is in charge of the organization; E. L. Campbell is chief chemist; R. B. Stringfield is in charge of chemical and H. L. Glaze of the mechanical engineering problems.

Would Platinum Registration Be a Safeguard Against Theft?

NUMEROUS large platinum thefts in recent months again emphasize the importance of some drastic measures to forestall further activity of the clever operators who have been so successful recently. One of the most effective proposals to this end which we have heard has been advanced by Dr. W. F. HILLEBRAND, Chief Chemist of the Bureau of Standards, to the effect that some form of platinum registration should be required.

It is recognized by Dr. HILLEBRAND that there are many complications and possible difficulties, and no one has yet suggested exactly how such a plan can be carried through most effectively and safely. It is an important proposal, however, and one which is worthy of very careful attention by everyone interested in the platinum industry whether he is a manufacturer or a user.

An ideal regulation would have national scope and effect, but of course anything affecting commerce in platinum could not legally be adopted by Congress except on the basis of affecting interstate commerce, and much traffic in platinum, of course, is intrastate. It is believed, however, that a registration could be required under internal revenue regulations if a nominal tax upon platinum sales were imposed. Such taxes could be made very nominal, perhaps one-tenth of 1 per cent, and thus amount only to enough to pay the costs of operating the registration agencies. It would thereby put no financial burden upon either manufacturer or user of the metal and the principal objection would be the possible complications and delay in the commercial handling of the material.

However, it is probable that everyone—producer, manufacturer and user—would be benefited despite these restraints, for the recent losses of platinum have been appalling. The Bureau of Standards lost more than \$10,000 worth of metal on one occasion. The University of Missouri and the University of Michigan also suffered losses. The largest loss of all recently reported is a \$40,000 theft from one of the manufacturers in the neighborhood of New York City. Certainly with these hazards accompanying the storage and use of platinum metal, we are justified in encouraging some inconvenience in the traffic. Under the circumstances, it appears that the proposal that all platinum sales should be registered with some appropriate agency is the best solution yet made. In any event, we urge careful consideration of this possibility in the hope that a really effective basis for protection of platinum metals can be developed.

Discussion of the subject by our readers is cordially invited.

A Plan to Co-ordinate University Scientific Research

CONFLICTING testimony on the subject of scientific research in our universities is offered in the annual reports of the president of the Carnegie Foundation for the Advancement of Teaching and the Committee on Chemistry of the Society for the Promotion of Engineering Education. The former is of the opinion that "in the sharp competition for the reputation supposed to come to a university from carrying on research the obligation to teach has become less and less realized, and the teaching of undergraduates, in some of our great institutions, is poor." The Committee, on the other hand, while recognizing frankly the poor quality of much of our instruction, attributes it more to the unceasing grind of class and laboratory work to which instructors are held, and the consequent lack of time for vitalizing research. Perhaps the two views are not strictly comparable, as President PRITCHETT undoubtedly has reference to the larger institutions in which contact between professor and student may be very limited, while the Committee certainly speaks for the smaller institution and the overworked instructor. Both are in agreement on two things: the prevalence of poor instruction and the necessity for research. With the former we will not concern ourselves for the moment, vital though it is; but the latter suggests some constructive comment.

President PRITCHETT says that "the development of a true spirit of research is a necessary part of every true university." And the Committee reports that "more research work must be done at many of the smaller institutions if their teaching staffs are to continue fit to train even undergraduates for the industrial world." With this indorsement, from which few will dissent, we may proceed to examine how best to vitalize research in the educational institutions of the country. The first thing that impresses even the casual observer is that there is no apparent co-ordination of the efforts at research in the different schools; that the subjects for investigation depend on the predilection of the professor, and are likely to be of little or no value; that unimportant subjects for research are often selected in ignorance of gaps in our knowledge that might better be filled; that from a national point of view, at least, there is no definite correlated program, and that much energy and ability are expended aimlessly. This is not framed as a harsh indictment, but merely stated as a condition.

The idea of co-ordinating university scientific research throughout the country is not new, having been the subject of much informal conversation and correspondence. But the time and conditions seem appropriate for the formulation of a definite program toward

that end. The first requisite is a central medium or clearing house, and that is at hand in the National Research Council. This body is cognizant of numerous problems of exact scientific nature or industrial utility that could be apportioned among institutions according to their equipment, physical and mental. The predilection of the investigator might still be catered to, but there would be correlation of his work with that of others and a systematic effort to obtain useful information. The demands of the war showed lack of knowledge along many lines, and the experience of those days can be turned to good account in this way.

The service of such a program to science and industry is but one of the benefits that will result, if we may take the opinion of the Committee on Chemistry previously referred to. It believes in the plan on account of the new vigor it will instil into college and university teachers; for the good example it will set for senior and post-graduate students; and for the influence it will have in retaining good men in the teaching profession. It has already recommended the plan to the National Research Council, and it has received favorable consideration. To us it seems like an excellent opportunity to mobilize a vast amount of energy and ability and train it for great usefulness, and for that reason we are glad to lend our support and encouragement.

Miami Copper Co.

Not in Contempt of Court

THE District Court of the United States for the District of Delaware, HUGH M. MORRIS, Judge, has dismissed the petition of Minerals Separation which sought to have the Miami Copper Co. punished for contempt of court and restrained from further use of its present processes. The order of court is reviewed elsewhere in this issue. It will be observed that, in effect, this order is the same as that of the United States District Court of Montana, dismissing Minerals Separation's petition to find the Butte & Superior Co. in contempt. In that case, it will be recalled, the plaintiff was "remitted to some one of the familiar methods to secure determination upon the merits of these alleged infringements," and was not "permitted to transfer the controversy from merits to contempt." In other words, if Minerals Separation believes that both Butte & Superior and Miami companies are infringing with their present processes, the way is open for new litigation to prove its contentions.

A further order by the District Court at Wilmington making Minerals Separation North American Corporation an additional party plaintiff has an important legal technical bearing in connection with the disclaimer regarding claims 9, 10 and 11 of U. S. Patent 835,120, which are the "small quantity of oil" claims not sustained by the Supreme Court. The question at issue is whether the failure of Minerals Separation North American Corporation to join in the disclaimer might not possibly have the effect of completely destroying the disclaimer and consequently throw out of court all infringement suits so far brought under this patent. Judge MORRIS gives leave to file a supplemental bill making Minerals Separation North American Corporation an additional party plaintiff, but without prejudice to the Miami company to renew its objection to the bill when filed.

Relations Between Institute of Metals, The Foundrymen and Mining Engineers

THOSE men actively interested in the Institute of Metals received something of a shock when they heard that the American Foundrymen's Association had decided to solicit papers on non-ferrous foundry practice, and had appointed a strong committee to attend to this work. They recollected that thirteen or fourteen years ago the American Brass Foundrymen's Association was organized, somewhat as an offshoot from the American Foundrymen's Association, the originators being men who felt that the older body was neglecting the non-ferrous field, especially from the point of view of physical metallurgy. The name was later changed to the American Institute of Metals, and the society bade fair to duplicate the wonderful success of the Institute of Metals, its British junior, certainly with no overwhelming advantage in size of industry or number of personnel to aid it.

In all the years of its existence the American Institute of Metals had made efforts, not without considerable success, to bring out papers and discussion on the so-called "practical" aspects of founding. However, only one who has tried it can realize the difficulty of securing such contributions from men who are qualified by experience in their subject, but not in literary accomplishment. Naturally, then, the *Proceedings* contained more and more pages written by men who were investigating the properties of alloys with microscope, pyrometer and all manner of physical instruments, and who were constantly finding new facts well worth recording, rather than by men who were attempting to establish the best balance between pouring temperature, furnace losses and scrap production, and attaining an approximate solution largely by intangible and indescribable refinements in skillful manipulation. "Scientific" men thus have a double advantage over "practical" men. In the first place, they write more, and practice makes it easier. In the second place, it is far easier to describe a thermal experiment precisely with the help of a cooling curve than it is to describe the proper way to gate a particular casting, even with a dozen sketches.

Meantime the 300 to 400 non-ferrous establishments represented in the American Foundrymen's Association became insistent for papers more nearly applicable to routine problems in the brass, bronze or white-metal foundries, and it was therefore resolved to attempt at least one such session at the annual meeting. Since the fall meeting of the Institute of Metals had been held simultaneously with the Foundrymen, to get the advantage among others of their annual exposition of mechanical appliances, the resolve was communicated to them. Feeling the great difficulty of securing such desirable papers, yet the distinct gain which such discussions should have, no matter from what source, the Institute of Metals decided to work hand in hand with the senior association and to pool their resources so that a real event could result. In this case duplication of effort is apparently needed before even reasonable returns can be expected.

For "American Institute of Metals" the reader should think "American Institute of Mining and Metallurgical Engineers, Institute of Metals Division," in what precedes, since we all know that the two institutions joined forces over a year ago. Whether the fusion was an altogether happy move is a matter on which two opin-

ions may be had; but since it is an accomplished fact all well-wishers of the Institute of Metals and all members of the Mining Engineers who are interested even mildly in the physical metallurgy of alloys should make it a point to see that they are enrolled in the Institute of Metals Division. At present there are many opportunities open whereby such enrollment may be escaped, yet to be specifically a member of the Institute of Metals Division involves no additional financial obligation. It does not exclude the member from participation in any other section or activity whatever of the parent society, but on the other hand it does admit the holder to valuable joint meetings, exhibits and other activities with the Foundrymen's Association as already outlined, will group the member with the leading Americans working with the metallurgy of alloys, and will help perpetuate the identity and influence of a quite honorable and very useful organization.

Steel Industry Functions Well During the First Half of 1920

IN a very trying half year the steel industry of the United States has made an excellent showing. The production was considerably less than the capacity, but the proportion of output to capacity was much higher than in many other industries. It has been made clear that when there are such difficulties as shortage of labor and inefficiency of labor the production of steel is less affected than the consumption of steel, taking the various lines of consumption as a whole.

When it comes to transportation, furthermore, it is seen that a breakdown there does not affect the operation of blast furnaces and steel mills as much as it does business in general. It is true that the steel mills reached the middle of the year with a large quantity of steel unshipped, but the reference here is to the production of iron and steel rather than the delivery. The accumulation of unshipped steel, indeed, reflects credit upon the industry, for the influence of the accumulation would be to restrict production. The manufacturers have shown ingenuity and courage in piling up the steel that they could not ship.

As to actual tonnage, it seems fair to take the steel-ingot producing capacity of the country at 50,000,000 gross tons a year. The half year's production of steel ingots was approximately 21,000,000 tons, or about 84 per cent of previously estimated capacity. And the 50,000,000-ton estimate cannot be considered a low one, seeing that in both 1912 and 1913 the actual production was only a shade over 30,000,000 tons, while the capacity existing at the close of 1913 could not possibly be estimated at over about 35,000,000 tons, so that 50,000,000 tons capacity at the beginning of this year would represent an increase during the war of 43 per cent.

The production of finished rolled steel, in the forms for which the statistics are gathered, normally runs about 76 per cent of the ingot tonnage, on account of scrap and scale losses, the material being eventually recovered very largely, but in the past half year the production probably fell a few hundred thousand tons short of the 16,000,000 tons that this proportion would give. Rather than curtail production of ingots and pig iron further, the mills accumulated ingots and semi-finished steel, thus showing courage and a willingness to perform.

The accumulation of semi-finished and finished steel at mills may be guessed at about 2,500,000 tons, the bulk of this being in finished product, rolled to customers' specifications, this representing between 12 and 15 per cent of the production, the accumulation occurring chiefly during the second quarter of the year.

Even the automobile industry, which has paid fancy wage rates and offered competition with other manufacturers that has been much complained of, can hardly show anything like a ratio of production to capacity of 84 per cent. Some manufacturing industries have been almost completely stalled in the past two or three months. As to the railroads, the output in transportation in proportion to physical facilities has been very low, yet it is now admitted by such men as DANIEL WILLARD that the railroads must do much better, in point of efficiency, than their best records of the past. This reference is only to quantity of transportation, in ton-miles. The quality has been particularly low, in point of there being such serious delays and such an ill-assorted movement. The steel industry probably made as good a record in quality as it did in quantity.

Chemical Engineering and The Motion Picture Industry

IN THE development of artistic motion pictures, improvements in projection apparatus and in the art of photography have played an important part, but without the highly developed film which is now available, and lacking photographic chemicals and dyes of excellent quality, it is doubtful whether the "movie" would have become as popular as a form of entertainment. The first requirement, of course, is a film of uniform and excellent quality. The research chemist and the chemical engineer have contributed largely to the results which are now obtainable. There remains, however, an opportunity for the development of materials and apparatus which will make possible the production of better pictures and considerably extend their field of usefulness. The production of non-flammable film is a problem that remains unsolved and the projection of pictures in colors would enhance both their educational and their artistic value.

There is no doubt that should an inexpensive non-flammable film be forthcoming, there would be an increased use of motion pictures, because of their educational value, by schools and by industrial establishments; this would create a demand for an inexpensive, light-weight projection apparatus that could be carried about easily and be operated by electric current obtained from a lamp socket. Even with the film and projection apparatus now available motion pictures have demonstrated their value as aids to the selling of heavy machinery and non-portable mechanical equipment and have been used as an aid to research in metallurgical and other investigations. These are but more obvious possibilities.

For such uses the cost of producing the finished film becomes an item of importance. A description of the production of motion-picture film is given on another page of this issue. It will serve to call attention to a field in which the chemical engineer can render a valuable service to a growing industry.

Fries Made a Brigadier General

IN DESIGNATING Amos Alfred Fries as the head of the Chemical Warfare Service under its new status, provided in the Army Reorganization Act, it is a generally held opinion that the Chief of Staff conferred this distinction upon one who is highly deserving of the honor and entirely capable of discharging the responsibilities of the position. According to the terms of the act, the rank of Brigadier General is bestowed upon the director of the Chemical Warfare Service. Thus, for a second time, Colonel Fries has attained the rank of General. His first commission as Brigadier General was awarded in France Aug. 16, 1918, when he was placed in charge of the chemical warfare section of the American Expeditionary Forces. With the demobilization of the Army, he was returned to his permanent rank of Lieutenant Colonel of Engineers. Since the resignation of General William L. Sibert, he has directed the work of the Chemical Warfare Service with that rank.

When, in August, 1918, he was made chief of the Chemical Warfare Service in France, General Fries was faced by tremendous odds. There was much indifference toward gas, both at home and among the officers of the Expeditionary Force in France. The American Army had little knowledge of gas warfare and gas was regarded as an unimportant factor in the situation. There was not a gas mask in the possession of an American soldier. The searching out and training of officers with a knowledge of chemistry was a most difficult task in itself. Under the stress of those exciting days, the building up of a personnel of the gas service was accompanied by perplexing delays.

Once the nucleus of his staff was formed, General Fries attacked the problems of obtaining supplies, building repair factories and providing for the manufacture of gas shells. Miracles were worked in the old French caserne at Chaumont. It took the most determined efforts to secure anything like the necessary volume of supplies and every increase in personnel was opposed. The accomplishments of those early days, however, attracted wide attention in the Army. The Germans were resorting more and more to the use of gas. The spirit of indifference to General Fries's service disappeared. The Army turned to him, not only for protection from the ravages of the German gas troops but for plans for fighting gas with gas. On the day the armistice was signed, General Fries's command consisted of more than 600 officers and 3,000 men. (An expansion was about to be undertaken which would have given the Chemical Warfare Service 1,600 officers and 18,000 men.)

Despite the trials and vicissitudes which accompanied the building up of the Chemical Warfare Service, General Fries remarked the other day that nothing in his experience with the American Expeditionary Forces so put him on his mettle as did the carrying out of the command given him personally by General Pershing during the Moro campaign in the Philippines.

General Pershing at that time was a Captain of Cavalry, and during the Philippine campaign he set out on a small expedition against the Moros. His engineer officer was First Lieutenant Amos A. Fries. Contact with the Moros was established in due course, but the wily savages had taken a stand beyond the narrow arm of the lake. General Pershing directed that bamboo rafts be made so that the intervening waterway could be crossed. The building of the rafts came under the jurisdiction of the engineer officer, as did the opening of the passage through a dense cover of water lilies. While cutting this passage, Lieutenant Fries and a raftload of enlisted men became so befouled by the lily growth that they could neither go ahead nor return. The Moros were quick to take advantage of the situation and for more than two hours Lieutenant Fries and his men were under the fire of the tribesmen. Finally they cleared the channel behind them and were able to return to their own forces without casualties. The difficulties of that situation have continued through the years to overshadow any other tight place in which General Fries has found himself. General

Fries can boast of an honor which all Presidential aspirants covet. He was born in a log cabin. It was situated in Vernon County, Wisconsin. His early education was obtained in that neighborhood. His parents later moved to Missouri and finally to Oregon. In 1893 he was graduated from the Medford, Ore., high school. He taught school for a year, trying to devise some plan of entering the Army—an ambition he had cherished since boyhood. The opportunity came in the form of a competitive examination arranged by the Congressman from his district. As the successful candidate, he received an appointment to the United States Military Academy, from which he was graduated April 26, 1898. He was just in time to enter the war with Spain. He served throughout

the war as Second Lieutenant of Engineers. He became a First Lieutenant Feb. 2, 1901; a Captain, June 11, 1904; a Major, Feb. 27, 1912, and Lieutenant Colonel, May 15, 1917.

From Jan. 22, 1911, to June 10, 1914, General Fries was the director of military engineering at the Engineer School at Washington Barracks. He also served for a time as business manager of *Professional Memoirs*, the official publication of the Corps of Engineers, and was, for two years, the editor of that magazine. General Fries was forty-seven years old on March 17.

No more fitting tribute could be paid to him at this stage of his career than to place him at the head of the Chemical Warfare Service, for it was largely due to his energy and zeal that the Army was brought to a realization of the importance of this branch of the service. That he will have the cordial and loyal support of the entire personnel in the service is quite as certain as that he will inspire his subordinates with his own enthusiasm. Both the Army and the chemical industry are to be congratulated on the fact that chemical warfare is in the hands of an officer who is both competent and sympathetic.

BRIGADIER GENERAL A. A. FRIES
Head of the Chemical Warfare Service

Uncovering the Platinum Theft at the Old Hickory Powder Plant, Jacksonville, Tenn.

A Chemical Detective Story in Which Scientific Facts Furnished Clues Enabling the Authorities to Apprehend the Source of the Platinum—Chemical Composition of the Stolen Material a Determining Factor

BETWEEN 4:30 p.m., March 17, and 9 a.m., March 18, 1920, almost 2,200 grams (73 troy ounces) of platinum laboratory ware, mainly crucibles, crucible covers, and dishes, was stolen from the Chemistry Building of the Bureau of Standards. The value of this ware at the time of the theft was nearly \$11,000. The matter was reported to the local police authorities, who immediately commenced an investigation.

During the first week in April information was received through the newspapers and also from the Washington police of the arrest in New York of two men, giving their names as Robert E. Carter and Joseph Fredericks, who were attempting to dispose of about 280 troy ounces of platinum sponge. Lots of 50 oz. and 10 oz. had been left at the offices of two concerns in New York which deal in platinum and the other noble metals. The remainder of the sponge was later found in two rubber hot water bottles in a small grip checked at the hotel where the two men were registered.

CHARGED WITH THEFT FROM CHEMICAL COMPANY

It developed that a certain detective agency had distributed a circular advertising the theft of platinum from the Roessler & Hasslacher Chemical Co., of Perth Amboy, N. J. The metal lost by this company included pure iridium sponge, platinum sponge, platinum sheet, and alloys of platinum and iridium containing 10 and 15 per cent iridium, as well as a considerable amount of gold and silver. This theft occurred between Dec. 26 and Dec. 29, 1919, and a reward of \$5,000 was offered for the return of the metal. The circular mentioned was in the possession of the two concerns to which the platinum sponge had been offered by Carter and Fredericks. The New York Police Department was notified and the men were arrested and subsequently detained, under \$5,000 bail, the charge being that the platinum in their possession was stolen from the Roessler & Hasslacher Co.

Acting on the idea that the platinum in question might include that taken from the Bureau of Standards, the Department of Justice was asked to investigate the matter. At the suggestion of this Department, Dr. E. Wichers, of the platinum laboratory of the Bureau of Standards, was directed to assist in this investigation in New York, working with the office of the United States Attorney and the Bureau of Investigation, U. S. Department of Justice.

SAID PLATINUM WAS MINED IN ONTARIO

In the preliminary hearings, Carter stated that his connection with Fredericks was merely casual and that he had obtained the platinum by placer mining on an unregistered claim in a region about 100 miles north of Parry Sound, Ont. The mining was done by Carter and an associate named H. H. Brooks. The platinum

was brought into the country without declaration to the customs officials. Carter claimed to be a native Canadian and stated that he had been in the United States only on one or two occasions for a very few days. It was noted, however, that he spoke with a marked Southern accent. It was also observed that he wore a silver belt buckle bearing initials "H. H. B." It seemed probable, therefore, that Carter's real name might be Brooks, especially as Carter failed to account for the belt buckle in a satisfactory manner.

Carter gave certain references in Ontario which were investigated by an agent of the Roessler & Hasslacher Co. and found to be false. One of these references gave the name of the Maxwell House as a hotel in Parry Sound. It was also known from statistics of the U. S. Geological Survey that the total annual production of placer platinum in Canada did not exceed 25 oz., and furthermore, that no placer mining of platinum was carried out in Ontario at all. This was subsequently confirmed by the Canadian Department of Mines.

MINING VENTURE STORY FLIMSY

In an interview with the representatives of the Bureau of Investigation and the Bureau of Standards, Carter gave some of the particulars of his mining venture in Ontario and described how "Brooks" had removed the gold from the crude platinum and had then converted the remainder to sponge by dissolving it in aqua regia followed simply by drying and direct ignition of the chloride solution. This was done on the scene of the mining operations with reagents and equipment brought from Trenton and Montreal for this purpose. The story was flimsy enough at best but it was obvious that a chemical analysis of the sponge would clearly distinguish between platinum that had undergone even the simplest refining and the crude mixture of platinum, iron (10-15 per cent), osmiridium and sandy matter which would result from platinum ore treated in the manner described.

It seemed probable, further, that an exact analysis of the seized platinum might help to decide the real origin of the metal in the event that Carter's story should be completely overthrown. Most of the platinum stolen in Perth Amboy was alloyed with 10-15 per cent of iridium. It was estimated that the laboratory ware lost by the Bureau of Standards would contain an average of about 1 per cent iridium, with less amounts of rhodium and probably some palladium and iron. Assuming that very little, if any, refining had been done on the platinum after it was stolen, a simple determination of iridium would have been sufficient to distinguish between these two lots of metal. Accordingly a sample for analysis was obtained from the Police Department.

It was obvious that either the laboratory ware stolen from the Bureau of Standards or the sheet metal taken

from the Roessler & Hasslachner Co. would have to have undergone solution and reprecipitation to arrive at the sponge form of the metal found on Carter. This might involve some change in composition. It was also possible that the seized sponge represented several lots of stolen platinum. It was to be expected, therefore, that the results of the analysis would be of greater value in pointing the way in which the investigation of the theft was to be directed than as testimony in the argument of any particular case.

As already stated, the Roessler & Hasslachner Co. had proved false the Canadian references given by Carter. In fact, the whole of Carter's story was discredited without much difficulty. Since it was impossible, however, to establish any direct connection between Carter or Fredericks and the theft of their platinum, the next step in the argument was that the weight of platinum in Carter's possession was very nearly the weight of the platinum itself which had been stolen from the Roessler & Hasslachner Co., considering that all of the platinum had been carefully refined out of the platinum-iridium alloys. Since no thefts of equal magnitude had been reported, these arguments were presumably sufficient in the minds of the Grand Jury to bring an indictment. Carter and Fredericks were held in the Tombs awaiting trial on this indictment at the time of the developments to be described later.

PLATINUM THEFTS REPORTED IN THE UNITED STATES

Incidentally it may be stated that the weight of platinum taken in nine separate thefts, all from the laboratories of educational and state and Federal scientific institutions, that have been reported to the Bureau of Standards, is about 240 troy ounces. These thefts were all committed since April, 1919, and range from 75 g. to over 2,400 g. in separate cases. Three of the cases represent a total of 205 oz. Adding 342 oz. of platinum and iridium stolen from the Roessler & Hasslachner Co. and about 3 oz. from another industrial concern within the same period, there is a total of about 585 oz., to which the nominal value of \$100 an ounce may be assigned, which had been stolen in about fifteen months and is as yet unrecovered. A few other thefts have since been reported. This is entirely apart from the case to be described in subsequent paragraphs.

To aid in the solution of the general problem of platinum theft, the Department of Justice is anxious to receive information concerning the attempted disposal of large quantities of platinum in any part of the country.

As was pointed out above, no single theft that had been reported was of sufficient magnitude to account for the weight of platinum in Carter's possession. It was, of course, possible that the rightful owners of Carter's platinum had not reported or possibly had not even detected their loss. At any rate, it seemed clear enough that Carter had not come into possession of the platinum in a legitimate manner. For this reason the U. S. Customs Service was preparing to bring action against Carter, in the event of his acquittal, on the ground of his own statement that the platinum had been brought into the country without declaration.

In discussing the entire case, Mr. Schauwecker, of the U. S. Assay Office, who has a very intimate knowledge of the distribution of platinum for war-time uses, made the suggestion that the platinum in question might have been taken from one of the Government munitions

plants. Certain of these plants manufactured sulphuric acid by the contact process and used thousands of ounces of platinum for this purpose. The platinum used in the plants built during the war was refined by the U. S. Assay Office and was converted to chloride solution either by the Assay Office or by the company which operated the plant. The diluted chloride solution was used to impregnate granular magnesium sulphate, giving the needed catalyst for the manufacture of sulphuric acid. Owing to the fact that some of these plants were no longer in operation and were in the process of being salvaged, it seemed not impossible that an undetected theft had been perpetrated.

WAR AND NAVY DEPARTMENTS TAKE INVENTORY

Acting upon this idea, the Bureau of Standards stated the case to the Chiefs of Ordnance in the War and Navy Departments and suggested that an inventory be taken of all the platinum in their possession. The Intelligence Bureaus of both Departments were asked to determine whether anyone known by any of the three names so far applied to the prisoners had ever been employed in any Government munitions plant. Through the efforts of the Washington police, Fredericks had been identified in the National Bureau of Identification as having a police record in Detroit for a minor offense. Carter had no previous criminal record, as far as could be learned.

The investigation by the Intelligence Bureaus yielded no information pertinent to the subject. In the course of a few weeks word was received from the respective Bureaus of Ordnance that the survey of platinum had been completed and revealed no shortage. Owing to the fact that most of the platinum held by the War Department plants was still in the contact mass, it was apparent that the actual amount of platinum on hand could not have been determined and that as a matter of fact this could not be done without a very extensive series of assays or a complete recovery of the platinum in the mass. This was acknowledged to be true by officials of the Ordnance Bureau.

ANALYSIS OF CARTER'S PLATINUM

In the meantime, the analysis of the sample of Carter's platinum had been completed by the platinum laboratory of the Bureau of Standards. The results were as follows:

Total platinum metals	Per Cent
Loss on ignition in porcelain crucible over blast lamp (volatile matter)	99.20
	0.67
	99.87

Analysis calculated on "non-volatile" basis, i.e., 100 per cent metals:

Iridium	Per Cent
Rhodium	0.33
Iron	0.10
Platinum	0.01
	99.56
	100.00

Gold, copper and nickel were not detected. Spectroscopic examination revealed the presence of a trace of palladium, as well as small amounts of aluminum, titanium and magnesium. Traces of calcium and strontium, and possibly of silicon, were found. The platinum sponge in Carter's possession was apparently homogeneous except for the presence of small lumps of

a yellowish brown substance which on ignition yielded platinum sponge and gave off chlorine fumes. A microscopic examination of the product of the ignition of these lumps and of the main mass of sponge was made by Dr. E. T. Wherry, of the Bureau of Chemistry. This examination showed the sponge to be of an indefinite structure except for the presence of groups of well-defined octohedra which were judged to be pseudomorphs after crystals of ammonium or potassium chloroplatinate. The potassium line had not appeared in the spectrum of the sample and the conclusion seemed warranted that the platinum had been precipitated as ammonium chloroplatinate from a solution of the chloride, and the precipitate ignited to sponge. It is to be noted, however, that the octohedral crystals made up only a portion of the mass of the sample. The brown lumps seemed to be incompletely ignited ammonium chloroplatinate and revealed the fact that the conversion of the yellow salt to platinum sponge had been carried out with inadequate facilities or in haste.

METAL OF UNUSUAL PURITY

The main thing to be learned from the chemical analysis as given above was that the platinum was of unusual purity. The very low percentage of iron was especially indicative of this. The low iridium content of the sample was very strong evidence that the platinum did not originate from the platinum-iridium alloys taken from the Roessler & Hasslacher Co. It was entirely improbable that the stolen alloys would have been subjected to sufficient refining to attain the purity indicated by the analysis. The same reasoning tended to eliminate the platinum ware lost by the Bureau of Standards or any other chemical laboratory, inasmuch as this ware contained a probable average of 1 per cent of iridium. It became doubtful, therefore, that further work on the case in hand would yield any results bearing directly on the Bureau's loss. Nevertheless, to aid in the proper administration of justice and to protect the legitimate users of platinum throughout the country, it was decided to continue the investigation.

In addition to the facts already stated concerning platinum-iridium alloys and platinum laboratory ware, it was known that nearly all other platinum of commerce usually contained from 0.5 to 1.0 per cent iridium, if not more. It is true that in the last two or three years the rising price of iridium has caused renewed efforts on the part of refiners to remove nearly all the iridium before allowing platinum to go on the market. However, nearly all the crude platinum which came into the country during the war was handled and refined by the U. S. Assay Office. From the analysis of samples of platinum prepared by the Assay Office and from communication with its officials it was known to the Bureau of Standards that a very high standard had been reached in this refining. Platinum 99.9 per cent pure and better was turned out in large quantities for the Nitrate Division of the Ordnance Department. (Most of this was subsequently alloyed with 1 per cent of iridium.) It was learned that the 5,800-odd oz. of platinum sponge prepared for use in sulphuric acid manufacture at the War Department powder plant at Nitro, W. Va., and the nearly 13,800 oz. for the plant at Jacksonville, Tenn., were also of high purity except that some of the platinum for use at Nitro contained about 0.5 per cent palladium. In view of these facts it was difficult to banish the idea that Carter's platinum came from one

or the other of these plants, especially in view of two "clues" which might otherwise have seemed irrelevant.

It will be remembered that Carter had referred to a "Maxwell House" as a hotel in Pagry-Sound, Ont. Though this reference was false, it was thought probable that he mentioned the name of a hotel which did exist in some other locality, rather than that he invented a purely fictitious name. It was found that a "Maxwell House" was a well-known hotel in Nashville, which is about fifteen miles from the powder plant at Jacksonville. On the occasion of a second visit to New York on May 6 and discussion of the case with the police, it was learned that at the time of Carter's arrest he had in his possession a cake of soap bearing the stamp of the Ruffner Hotel of Charleston, W. Va., a city in the immediate vicinity of the plant at Nitro. The soap also bore the initials "H. H. B." cut into it with a pocket knife. Failing to obtain any information from the police at Charleston, the New York detectives had apparently abandoned this clue.

It seemed, however, that these two things established positive connection of Carter with Charleston and possible connection with Nashville. This information was used by the Department of Justice agents at Charleston and Nashville in a new attempt to connect either or both of the New York prisoners with these plants. Since the three names ascribed to the subjects did not appear on the employment rolls, and since there was no apparent shortage of platinum, no ground was gained in this way.

COMPANIES HAD EMPLOYEES' PHOTOGRAPHS

It was reported by the Ordnance Department that the Hercules company and the du Pont company, which had operated the plants at Nitro and Jacksonville respectively, had on file at their headquarters offices at Wilmington complete employment records, together with photographs of all employees. Since the agents of the Bureau of Investigation and the Bureau of Standards had seen both Carter and Fredericks, it was thought that an examination of the photographs of the employees would determine whether these men had been employed at either plant under different names than those they now gave. In this connection it should be stated that under the New York law it is impossible to take photographs of persons in custody until after their conviction. Fredericks' photograph had been obtained from his former police record and had been sent to Nitro and Jacksonville without being identified. No photograph of Carter was available to send to the plants and it thus became necessary to make this personal visit in the expectation of identifying him in the employment records of the two companies.

On visiting Wilmington, it was learned that most of the employment records and all of the photographs of employees had been returned to the local offices at the plants after the War Department had assumed active control. Believing that the evidence warranted the assumption that Carter had actually been in Charleston shortly before his arrest, it was decided to proceed to Nitro and examine the records there. Carter could not be identified and unfortunately the photographic files were not complete. Still confident of the logic of the deductions made from the chemical analysis of the platinum in question, the representative of the Bureau of Standards undertook to follow out what seemed to be the last possible lead and proceeded to Jacksonville.

The visit to the Jacksonville plant met with sudden success. Aided by what was really a fortunate accident, Carter was identified as H. H. Brown, who had been employed as a salvage foreman until his departure from the plant on March 27, on ten days leave. On April 20 he had been discharged for unexplained absence. While it seemed that Brown had had no possible means of access to the platinum stocks of the plant, the manner in which he had obtained the 280 oz. found in his possession was to be explained by the next important development, which followed within an hour after Brown's identification. This was the receipt by the Nashville office of the Bureau of Investigation of the following letters, which were written by a man in the Tombs prison in New York and addressed to his wife. The letters were intercepted and sent to Nashville from the office of the District Attorney of New York City, where it was believed that the letters had to do with the traffic in narcotics. The letters were published in the Nashville papers on May 30:

LETTERS FROM SUSPECT TO HIS WIFE IMPLICATE CRONE

May 14, 1920—Dear Wife: Just a few lines, hoping it finds you in the best of health as it leaves me, and I hope you have sent me that letter, and I have sent a letter to the lawyer to come down and see me, and I want you to call him up so to make sure that he will come down, and you should not worry about what I have said to Uddie. I did not mean to say that you are keeping the money for yourself. I know any time you have a dollar I could get it, so please don't take it up the way you mean. I will send Jack Noyer a letter and explain to him that you are sticking to me and that they could trust you with any amount of money, and I am going to try to lay my bit off for two weeks and then I will see what I should do, and Monday I want you to get ready to go out of town and when you are there you should tell this party that Robert Carter is under \$5,000 bail, and they will raise the bail to about \$15,000, and he should give you at least \$20,000 worth of stuff, and he should put them in 25 ounces in each package, and you could get about \$85 or \$90 an ounce. The reason why you are asking for that amount is because Carter will not be able to leave town as soon as he gets out on bail so he will hafta stay in New York a few days so that no one is folling him around, and he need some expense money, and he will jump bail and never come back to New York, and as soon as you get this stuff from the fellow you should get a vault and put the stuff in there. You could get a vault at the Bowery and Grand Street, and you could get for the stuff \$100 a ounce, and each package should bring you \$2,500, and the address is where the fellow is working at the Old Hickory Powder Plant, his name is H. R. Crone. Telephone of the place is Hadley 4601, when you get that number tell them to connect you extension 93 and if that ain't the wright number look up the telephone book for Old Hickory Powder Plant and this powder plant is about 20 miles away from the ceity and you should get yourself a round trip ticket to Nashville, Tennessee, and when you get there you should ask for a good hotel and you should ring him up on the phone and tell him you are the party from new York and you have a letter from Carter for him and he will come around to you in an auto and call for you. You are to ask him where he could meet you and tell him that everything is O.K., and that Carter is not saying a word and he trusted your husband as being that I can not get out so you made the trip for me, and tell him as soon as Carter gets out Carter will explain him what kind of a fellow I am to him and as I have no more to say I will close and send you my best regards and also with love. I remain yours husband, Joe. P.S. you do as I tell you you will be worth a big piece of money in a short time.

Old Hickory Powder Plant, H. B. Crone, Tel. Hadley 4601, Ex. 93; office hours from 8 to 4.

May 15, 1920—Dear Wife: Just a few lines hoping it finds you in the best of health as it leaves me and I have sent a letter out to Meyer for one of the boys I put in just as you have stated to me and I have sent a letter to my mother stating she would give you one

hundred dollars, but she will not get that letter until Monday and the fellow from the lawyer's office was down to see me and he could not get in so I send him the answer down what I wanted and before you get out of the house always look for mail and I hope you have received the two letters Saturday, one for yourself and the other one for the party out of town. And everything will be arranged for you when you get that party and may be you will hafta stay at the hotel a day or two. And you should make yourself that you are very wise and tell him that you have a buyer that will take all the stuff that he has at the price from 85 to 90 dollars a ounce.
JOE.

CRONE IS ARRESTED

Crone was kept under surveillance for several days until the agent of the New York office of the Bureau of Investigation obtained from Brown the confession that the platinum in his possession was obtained from Crone, who had stolen it from the reserve stock of platinum at the plant. Crone's arrest followed immediately upon Brown's confession. Up to the time of the present writing, Crone has denied any guilt in his handling of the platinum at the plant.

HOW THE THEFT WAS CONSUMMATED

About the first of March, Crone, as chief chemist of the plant, was directed to convert the reserve stock of platinum chloride solution, representing almost 2,300 oz. of platinum, to platinum sponge, place it in sealed aluminum cans, and transfer it to the custody of the accounting office, where it was placed in a safe inside of the vault in this office. About 75 oz. of platinum was handled at a time and the work was completed between the middle and the last of April. The safe contained eighty-eight of these sealed containers, each bearing a label indicating the weight of platinum (about 25 oz.) it contained. After Crone's arrest, the contents of these cans were examined. Of the eighty-eight cans, two contained platinum. One of these was the first one placed in the vault. The other represented a quantity of chloride solution which would only half fill one of the cans. The remaining eighty-six cans contained what appeared to be a mixture of mercury with ordinary moist dirt, the ratio between the two being carefully adjusted so as to fill the can completely and also give the correct gross weight to the sealed can.

REMAINDER OF PLATINUM TAKEN NOT YET FOUND

It is presumed that Crone's defense will be along the line that Brown is shielding the real thief, who gained access to the vault and made the substitution there. One of the most interesting details of Brown's confession was that Crone had directed him to sell some of the platinum in order to provide funds for Crone's defense "when the crash came." Brown disclaims any knowledge of the whereabouts of the platinum except that which was in his possession, which is the total amount that has been recovered to date. Crone and Brown had both worked in the Parry Sound, Ont., region. There was no evidence to indicate that Fredericks was implicated in the theft of the platinum or in the attempted disposal of it except that he acted as a guide for Brown in New York.

Examination of the register of the Ruffner Hotel at Charleston disclosed the fact that Brown registered there on March 28, the day after he left Nashville. It was learned that his stop at Charleston, while on the way to New York, was in the nature of a visit and apparently had no connection with the stolen platinum or the Government plant at Nitro.

Developing, Printing and Assembling of Motion-Picture Film

By L. W. CHAPMAN

AN IDEA of the size of the motion-picture film industry may be gathered from the statement that more than 270,000,000 lin.ft. of film valued at more than \$10,000,000 was exported from this country during 1919 and that an estimate of the total amount manufactured in the United States is given as in excess of two billion feet, valued at approximately \$75,000,000. As the process is carried out in the motion-picture laboratories, the cost of developing, printing and assembling approximately equals that of the cost of the film.

The description which follows is of the process as conducted in the two laboratories of the Famous Players-Lasky Corporation at Los Angeles, Cal., at which nearly a million feet of film is used per week.

Film as received from the manufacturer is without perforation and this, then, is the first operation per-

FIG. 1. DARK ROOM

formed in the laboratory. These perforations are made by automatic machines and the film, if to be used for negative, is wound in 400-ft. (122-m.) lengths on camera reels; if used for positive the film is wound in 400-ft. rolls and when printed is cut into 200-ft. lengths. Negative film has a silver bromide base, and that from which the prints, or positives, are made has a silver chloride base.

In the laboratory dark room the exposed negative is looped on cedar frames holding 200 ft. (61 m.) of film and on which the film remains throughout the operations of developing, fixing, and washing. Wooden developing tanks are used which hold 180 gal. (680 l.) of developer and accommodate five frames at one time. These slide in vertical grooves at the ends of the tank. The developing of the negative requires from twelve to fifteen minutes in a solution made up according to the following formula: Metol 1½ oz., potassium bromide 2½ oz., hydroquinone 5½ oz., pyro 2 oz., sodium sulphite 9 lb., sodium carbonate 4½ lb., water 80 gal. (42.4, 70.8, 148.8, 56.7, 4,082, 2,041 g. respectively to 303 l.). The bath is maintained at a temperature of from 18.3 to 18.8 deg. C., copper coils being provided through which warm or cold water can be circulated as required. In

FIG. 2. WASH ROOM

Fig. 1 is shown the operation of looping the film on frames, the inspection of a partly developed film and the washing of the developed film before fixing. The development is conducted so as to produce what is termed a "soft negative," the printing of the positive being relied upon to bring out contrasts. Development of the negative is in the hands of experienced operators and their judgment is relied upon to determine the degree to which it is carried.

After development is complete the film is removed from the tank, washed by immersing in a tank containing running water and transferred to a tank similar to the developing tank, containing the fixing solution which is made up as follows: hypo 800 lb., chrome alum 30 lb., sodium sulphite 32 lb., sulphuric acid 85 oz., water 300 gal. (363, 13.6, 14.5 and 2.4 kg. to 1,135 l.). Film remains in the fixing bath for fifteen minutes. From the fixing bath the frame is transferred from the dark room through a light-proof vestibule to the lighted washroom. The washing is conducted in two stages by immersing the frame in tanks containing running water, the flow of water being such that a complete change is made in five minutes, the operation requiring one-half hour. The washroom is shown in Fig. 2.

In drying the film much care is needed. The operation is carried out by revolving the film on reels. (Fig. 3.)

FIG. 3. DRY ROOM

These reels are made by spacing cedar slats about 8 in. (20 cm.) apart on wheels 4 ft. (1.22 m.) in diameter. The reels are 10 ft. (3 m.) in length and will carry about 1,200 ft. (36.6 m.) of film. The reels are revolved by means of an electric motor at 50 r.p.m. and the drying operation requires about three-quarters of an hour. In order to prevent the film from curling the rate of drying must not be too rapid and the moisture in the atmosphere of the dark room, the wash-room and the drying room is therefore maintained at about 60 per cent relative humidity by an automatic air-conditioning apparatus which washes, humidifies and circulates air through these rooms, and also maintains the room at a uniform temperature. Dust particles are a source of trouble, being a cause of "light specks," and in order to produce a film free from this defect it is essential that the air in the rooms be washed.

For the production of a five-reel story requiring 4,500 to 4,800 ft. (1,370 to 1,460 m.) of film, from 20,000 to 30,000 ft. (7,000 to 9,000 m.) of negative may be taken. After the negative is developed and dried a sample or "rush" print is made which the director, or "film editor,"

FIG. 4. NEGATIVE CUTTING AND ASSEMBLING ROOM

"cuts to the action." Titles and any directions for the dyeing, printing or toning of the positive are returned with the edited print to the laboratory. The titles are photographed from wash drawings and in the laboratory are treated the same as other negatives. The negative is cut to correspond with the "edited" positive and assembled together with the titles by scenes. (Fig. 4.) These are then cemented together in proper sequence in lengths of about 200 ft. and after inspecting, cleaning and dusting are ready for printing.

As a five-reel story may contain three hundred or more scenes many of which have been taken under varying light conditions there results variation in the density of the negative. It is important that uniform intensity of illumination be obtained when the film is projected on the screen. This result is accomplished by controlling the printing operation.

Since each scene is photographed under uniform conditions as affecting the lighting of the subject, the length of film representing one scene will produce when developed a negative of uniform density. Each scene is "light tested" to determine the amount of exposure to be given in the printing operation to produce a print of a standard density. The light test is carried out by

FIG. 5. PORTION OF A "LIGHT TEST" PRINT

printing a length of the negative from the first portion of a scene corresponding to that of twenty-two pictures or about 16½ in. film. This print is exposed by means of the "light test" box. This box is light-tight except for a ground glass top which is the width of the film and 16½ in. (26.7 cm.) in length. There is painted near the edge of the ground glass in small figures the numbers from 1 to 22; these are spaced ¾ in. (1.9 cm.) centers so that a number will be printed in each individual picture. A standard 40-watt frosted-globe tungsten lamp is placed at one end of the test box and about 4 in. below the ground glass. The illumination of the ground glass and therefore the amount of exposure of a positive made through the ground glass is then more intense at the end near the source of light, and a print will be obtained showing gradual increase in density from the picture numbered 22, which is nearest the lamp, to that numbered 1, which is furthest away. The time of exposure is automatically and absolutely controlled and is therefore the same for all tests. The test prints are developed for exactly three minutes in the standard developing bath, which is maintained at the standard temperature. These prints are fixed, washed and dried in the usual manner. A portion of a "light test" print is shown in Fig. 5. A "light test" card is made out for each reel of 200 ft. of negative and on this card are noted the scene number, a brief title of the scene and any directions for toning or dyeing of the print. The light test prints are inspected over a ground glass which is uniformly illuminated and the inspector selects the picture which has the desired density. The number which is printed in this picture is recorded on the light test card. (Fig. 6.) In making the light test a notch is cut in the edge of the film to locate the beginning of each scene and title.

The printing is performed in a Bell & Howell electrically operated printing machine. (Fig. 7.) The negative and the film to be printed are passed

FIG. 6. LIGHT TESTING

at a uniform speed by an aperture, the area of which may be varied and through which the film is exposed to the light from a standard 40-watt frosted globe tungsten lamp, the negative being pressed firmly against the positive by air pressure. The exposure aperture is of the same width as the film, but the opening in the other direction is controlled by the machine operator, the amount of opening being controlled by a lever, a pointer on the end of which swings over an arc on which are printed the numbers from 1 to 22. The printing operation is begun by setting the pointer to correspond with the number which was recorded on the light test card for the first scene. The light is turned on and the motor which winds the film through the printing machine is started. The negative before reaching the aperture passes through a device by which the notches which have been cut in the edge of the film at the beginning of each scene are made to sound an audible click. This click indicates that another scene is about to pass

FIG. 7. PRINTING ROOM

the aperture and the operator moves the pointer to the number on the arc which corresponds to the number given on the light test card for the succeeding scene. The printing is in this manner controlled so that a positive of uniform density is obtained. The machines print at a rate of 62 ft. (18.8 m.) of film per minute.

Direct current at constant voltage is used in the light test and printing.

The exposed print or positive is wound on frames and goes through the same treatment as the negative, using, however, a developer having the following composition: Metol 6½ oz., hydroquinone 64 oz., sulphite 14 lb., carbonate 20 lb., bromide 4 oz., made up to 80 gal. with water (184, 1,813, 6,350, 9,070, 113 g. respectively to 303 l.). After fixing and washing the film may be dyed or toned and these portions are printed and developed separately. The films are dyed by immersing in tanks similar to the developing tanks containing a water solution of the dyes. Several dyes may be used in sequence on the same film and it is possible to obtain from forty-five to fifty different tints from nine dyes in this manner. In addition to uniform coloring of the print, different tints for the high lights, half-tones and full tones may be obtained, depending on the relative adsorption of the dyes which result from variations in the thickness of the deposit.

After washing, the print is dried in the same man-

FIG. 8. INSPECTING ROOM

ner as the negative. The prints are assembled into lengths or "reels" of about 1,000 ft. (305 m.), dusted in vacuum dusters, projected to inspect for defects (Fig. 8), measured and packed in galvanized iron tins which are packed in wooden boxes for shipment.

It will be noted that a considerable amount of waste film results from the various operations. This is purchased by a company which collects the waste film from several of the studios. The silver deposit is dissolved from the film by means of "lye" or caustic soda, and the silver recovered. The same company also collects the solutions containing silver from the motion-picture laboratories and the silver from these is also recovered. Considerable quantities of the waste film are used by manufacturers of celluloid products.

We are indebted to Frank V. Biggy of the Morosco Studio of the Famous Players-Lasky Corporation, Los Angeles, Cal., for the illustrations, and for courtesies extended in the collection of these notes.

Engineers and Scientists in Westminster Abbey

MR. E. J. MEHREN, editor of the *Engineering News-Record*, who is traveling in Europe, has contributed to his journal the following interesting observations on a visit to Westminster Abbey:

Until yesterday I did not know that there was in Westminster Abbey a well-defined location for the tombs and monuments of scientists and engineers. We all know of Poets' Corner and of the Royal Chapels which contain the bones of many of England's kings and queens, but the engineers' and scientists' corner (an inadequate description for one spot in the quiet nave and in the north aisle) has not been celebrated in the descriptions of the Abbey that have come to my hand. Consequently I was the happier at the discovery.

Against the screen of the choir stalls, looking into the nave, is the monument of Sir Isaac Newton, while directly in front, well out in the center of the nave, are the tombs, under the pavement, of Telford and George Stephenson, Telford's marked by one of the small square pavement stones cut with his name and Stephenson's by a full length floor panel—a work of art in bronze. A statue of Telford stands elsewhere in the Abbey. What a fitting home for the long sleep of these master engineers! Above them springs the wonderful Gothic nave, airy in its lightness, yet built of stone—a sight such as I have never seen. The master builders of a later age lie asleep beneath the work of the master builders of all time, masters who outrivalled those of ancient Egypt or Greece or Rome—the Gothic cathedral builders of the thirteenth century. Egypt built great temples and mighty pyramids; so did Greece and Rome. But structurally the forms were simple. With the high-flung naves and crossings and choirs of the Middle Ages came engineering problems of no mean order. Yet so well were the principles understood that wonderful grace and appearance of lightness were secured. Today, with all our advances, we do nothing to equal their master works.

But to return to the engineers in Westminster: By the side of Newton, directly in front of the Newton monument, lies the body of the late Lord Kelvin, while 20 ft. to the north, in the aisle, lie, side by side, the bodies of Herschel, the astronomer, and of Charles Darwin. Above these vaults, casting on them a light mellowed by the art of the stained-glass worker, are a memorial window to Sir Benjamin Baker, the inscription recording two of his great works—the Forth Bridge and the Assuan Dam—and another to Lord Kelvin, "Engineer and Natural Philosopher," as the inscription has it. In this same north aisle are memorial windows, also, to Stephenson, Joseph Locke, designer of the Crewe engine; Brunel, Trevithick, and Charles William Siemens.

The Siemens window looks down on a group of tablets to scientists—to Lister, the physician; Darwin; Hooker, the botanist; Adams, the astronomer, and Joule, the physicist. The Joule tablet bears this inscription: "This tablet is here placed near the graves of Newton, Herschel and Darwin by those who in many lands have united to perpetuate the memory of James Prescott Joule, F.R.S., of Manchester, in recognition of services rendered to science in establishing the law of the conservation of energy and determining the mechanical equivalent of heat."

In the central part of the nave and the north aisle are buried other great men with kinship to engineers. We find the tomb of Sir Charles Lyall, the geologist. It is covered by a brass-lettered slab bearing this tribute: "Throughout a long life he sought the means of deciphering the fragmentary records of the earth's history, in the patient investigation of the present order of nature, enlarging the present boundaries of knowledge and leaving on scientific thought an enduring influence." Out in the center of the nave, near the graves of Telford and Stephenson, are four graves placed with singular appropriateness under this great nave—mortal remains of four architects who played an important part in the revival of Gothic architecture. They are Sir Charles Barry, architect of the Houses of Parliament; Sir George Gilbert Scott, George Edmund Street and John Loughborough Pearson.

As I turned to leave this part of the Abbey, after musing there an hour, I chanced to walk over the Telford inscription and my eye caught on the slab at Telford's feet the name of Livingstone—David Livingstone, the African explorer—and the thought struck me that he was in kindred company. He explored an unknown country; he extended the bounds of knowledge regarding a section of the earth's surface. So did Telford and Stephenson and Lyall explore the unknown; so did they, and their great fellow engineers and scientists about them, extend the bounds of knowledge. They, no less than he, were explorers of a dark continent and have placed humanity under tribute for all time.

London, May 9, 1920.

Expansion of French Chemical and Oil Industries

* The chemical industry of France continues to attract large amounts of capital and it is evident that it will become one of the leading industries of the country. Among recent company incorporations is found that of the Société Alsacienne de Produits Chimiques, with 16,000,000 francs (1 franc = \$0.193 normal exchange), capital to take over the former German-owned Kesther establishments at Thann-Mulhouse (Alsace) in addition to a large modern plant at La Rochelle, formerly making war chemicals, which will now be used for the manufacture of synthetic camphor, sulphates of copper and potash, and a trade-marked brand of butterine.

The distribution of petroleum, fuel, and lubricating oils is also receiving the attention of capitalists. Two companies recently floated by local bankers of La Rochelle for operation in this consular district are the Société pour l'Importation des Huiles Combustibles, capital 5,000,000 francs, and the Société de Fabrication de la Vaseline, capital 1,400,000 francs. Other late incorporation of companies to deal in chemicals and oils and their capitalization are: Société Française Ratoczyn (gasoline, heavy oils, carburents, etc.), 23,000,000 francs; Société Pax (essential oils and other chemical products), 1,000,000 francs; Société pour l'Approvisionnement des Consommateurs d'Huiles Combustibles, 2,500,000 francs; Société la Pétroléenne, 22,000,000 francs; Société Chimique et Industrielle des Monazites (chemicals and the manufacture of thorium, cerium, mesothorium, and other rare metals), 2,500,000 francs; Société des Hydrocarbures et Produits Industriels, 10,000,000 francs; Société de la Silice (pulverized silicates and an artificial product) 600,000 francs.

The soap and similar industries are expanding and many new companies are being formed.

Some Investigations in Briquetting Oklahoma Coal*

By J. C. DAVIS

TESTS were recently conducted at Oklahoma University to determine whether the briquetting of certain Oklahoma coals, using a crude oil residue as a binder, could be profitably carried on commercially. While the process in itself is not new, some interesting data were obtained.

BUREAU OF MINES RESEARCH

The Bureau of Mines has made extensive researches on the subject of briquetting and briquetting materials in its plants at Norfolk, Va., Pittsburgh, Pa., and St. Louis, Mo. Binders of various kinds were tried, including both inorganic and organic materials. Among the inorganic materials tried were clay, lime, magnesia, magnesia cement, plaster of paris, portland cement, natural cement, slag cement and water glass. Some of the organic materials experimented with were wood products, such as rosin, pitch and pine tar; sugar-factory residues such as beet pulp, beet sugar molasses, and cane sugar molasses; starches, tars and pitches from coal, such as blast-furnace tar, producer-gas tar, coal-tar creosote and various grades of pitches from various tars; natural asphaltum and petroleum products such as crude oil and crude oil residue. Anyone interested in these results may find a complete summary of the experiments in Bulletin No. 58 of the Bureau of Mines.

TESTS AT OKLAHOMA UNIVERSITY

The experiments made in the Materials Testing Laboratory, at the University of Oklahoma, were conducted by C. T. Griswold, mining engineer for the Atchison, Topeka & Santa Fe R.R., assisted by the writer, and it is with his permission that the data given herein are made public. After consulting the bulletin above referred to, it was assumed that a standard mixture should be made of 90 per cent moisture and a 7 per cent binder. The coal was then ground and thoroughly washed to rid it of slate and other impurities so far as practicable.

In order to carry out the tests a hollow cast-iron mold was made approximately $4\frac{1}{2} \times 4\frac{1}{2} \times 2\frac{1}{2}$ in., with a central hole of about $1\frac{1}{2} \times 2\frac{1}{2}$ in., with rounded corners. A base plate was made so as to have a projecting rim extending into this opening from the under side. A plunger, sufficiently long to compress the coal, passed down through the opening from the upper side. The mold was then filled with the coal and binder; the plunger was placed in position and the mold put under the compression head of the 100,000-lb. Riehle testing machine resting on the self-adjusting lower head. Trouble was experienced in getting the briquets to come free from the mold, due to the roughness of the casting, and it was decided to have the entire inside of the mold finished, together with the projecting portion of the base plate and the plunger. The briquets then came out freely, perfect in shape, and of a size to give a weight of approximately $2\frac{1}{2}$ oz.

A number of experiments were then made to determine the best pressure to use. Pressures were tried out varying from 1,000 to 5,000 lb. per sq.in. The former pressure seemed too low to compress the binder properly into the coal. At a pressure of about 2,000 lb. per sq.in.

the materials seemed to unite very satisfactorily. An increase to 3,000 lb. per sq.in. did not seem to improve the binding qualities materially and with pressures above this amount the particles of coal were crushed. It was therefore assumed that 2,000 lb. per sq.in. would be the proper pressure to use in the briquetting work.

TYPE OF OIL EMPLOYED

The binder used was a Wheeler crude oil. Tests were first made to see what reduction from the original volume would be necessary in order to give a satisfactory binder. Oil was reduced to 50 per cent of its original volume and continued by 10 per cent reductive steps down through 40, 30, 20 and 10 per cent. A 15 per cent grade was then made and found highly satisfactory. Briquets were formed using 5, 6, 7 and 8 per cent of each binder. In all cases the briquets were soft and could easily be crushed in the hand after having had time to cool completely and to harden until the 20 per cent reduction was reached. The 10 per cent seemed too hard and rather brittle, while briquets made from the 15 per cent were excellent.

The distillation test furnished by the oil company showed this crude oil to contain an asphalt base of 36 per cent—10 deg. penetration. The laboratory check made at the university showed the following:

STEAM DISTILLATION FIGURED ON BASIS OF DEHYDRATED CRUDE

	Per Cent
Kerosene distillate (40-5 deg. B ₆)	2
Gas oil (34-3 deg. B ₆)	14
100 viscosity (at 100 deg. F.) lubricating oil	21
Fuel oil (calculated)	43
Residue	15

A binder was then made at the Cameron Refining Co., at Ardmore, Okla., to meet these specifications and was found to check with the above distillation test. Further tests on this binder registered penetration 26 at 25 deg. C. by New York penetrometer, 50-g. weights being used for five seconds. The melting point as shown by the ball and ring method is 126 deg. F. These tests lead to the following final specifications:

An asphalt binder with a penetration of 20 and a melting point of 160 deg. F. to withstand the excessive summer heat of this section. It is safe to assume that any other asphalt answering these specifications would be equally satisfactory for use. It may be necessary in any case to require a slightly higher melting point.

THE COAL USED

The coal used in all these tests was ground to pass a 10-mesh after studying the action of $\frac{1}{4}$ -in. to 60-mesh. The 10-mesh did not seem to crush under the pressures needed for the purposes of satisfactory briquetting. The samples used were made from all coals passing a $\frac{1}{4}$ -in. round hole screen and contained both the slack and the finest dust mixed in the proper proportions of 31 to 9. Analyses of these coals showed the following percentages:

	Lehigh Unwashed	Lehigh Washed	Average Slack of McAlester-Wilburton
Moisture	2.30	2.79	2.04
Ash	19.54	12.10	10.93
Volatile matter	31.20	31.23	35.83
Fixed carbon	48.04	53.32	53.23
B.t.u.	10,710	12,200	

B.t.u. tests on the finished briquets showed the unwashed samples to contain 10,543 B.t.u. and the washed ones 12,570 B.t.u. Washing appears to increase the B.t.u. about 20 per cent.

Temperature and moisture variations were tried throughout the tests, temperatures being tried between

*Abstract from paper presented before the chemists and engineers meeting at Tulsa, Okla.

60 and 450 deg. F.; and moisture variations of from 3 to 10 per cent. It was found that the best results were obtained when the temperature was kept between 180 and 200 deg. F. When moisture contents between 3 and 5 per cent were used, there did not seem to be much difference in the quality of the briquets, but when 5 per cent was exceeded they showed voids and crushed much more readily.

Some of the briquets were subjected to rolling and drop tests. Twenty lb. of the briquets made from unwashed coal was placed in an oil barrel and the barrel rolled over the rough ground for two minutes at 32 r.p.m. These briquets showed a loss in weight of 3½ per cent. Some of them were then dropped from a height of 6 ft. three times onto a concrete floor and showed a loss of 1 per cent from this test. The washed briquets, then subjected to the same treatment, showed losses of 1½ per cent from rolling and ½ per cent from dropping. None of the briquets of either kind were broken into parts, the losses being due to breaking of the edges and corners. The height of the drop was then increased to 12 ft. and they were then broken into parts only on the third drop, showing in all cases clean cut cleavage planes. Any of the briquets tested were sufficiently strong to withstand the pressure of a man's weight as shown by placing them on the floor and stepping on them.

BURNING TEST

As the "test of the pudding is in the eating," so the test of the fuel is in the burning. A fire was made in an ordinary round heating stove having 3-in. grate openings. The fire bed was 8 in. deep. Both kinds of briquets kindled readily, burned freely, made no more smoke than an ordinary coal, and did not soften, disintegrate or fall through the grate bars during the process of combustion. The washed coal briquets, however, made a much hotter fire. The unwashed left a refuse of 28.7 per cent and clinkered badly, leaving a hard consolidated clinker. The washed coal briquets left a refuse of 11.6 per cent and showed only a small amount of soft clinker.

CONCLUSIONS

These tests show beyond doubt that the Oklahoma soft coal of the above grades can be successfully briquetted, will make a cleaner domestic fuel than the ordinary bituminous coals, and will stand handling and rough usage to a remarkable degree. As a locomotive fuel they would no doubt prove very satisfactory. The initial cost for a plant to make briquets of a desirable kind is high, but it is believed that these briquets can be made to sell at a price no higher than the better grades of bituminous coal and will give greater satisfaction to the consumer.

Losses of Crude Oil by Evaporation

A recent report of the Bureau of Mines makes the statement that "The evaporation of crude oil without doubt causes one of the largest single losses to which the oil is subjected after it is taken from the ground. The few days during which crude oil is stored on the lease before being taken by the pipe line causes an aggregate loss per year from evaporation estimated at 122,100,000 gal. of gasoline in the Mid-Continent field alone. This has a value, at 22c. per gal., of \$26,880,000 and represents about 3 per cent of the total gasoline produced in the United States from all fields and all sources."

Position of Nitrate-Producing Companies in Chile

The large Chilean companies are adding to their present holdings by buying out the smaller concerns and acquiring further nitrate deposits not yet worked. It is reported that some of the British companies desire to sell out because of burdensome taxation on their capital in England, but this cannot be verified. It is quite probable that if these companies would sell out it would be to some Chilean company and the property would be worked as before. The feeling in the nitrate industry in Chile at the present time is most optimistic, based on the probable demands from central Europe, principally Germany, which has always been a large user of nitrate as fertilizer, and the fact that the production of the artificial, or, rather, electrically manufactured nitrate, has not been so successful as anticipated and cannot compete with the natural product of the deposits in Chile either in price or quality.

PRICES OF NITRATE INCREASE

There have been several reasons why the nitrate-producing companies did not show large profits last year, the principal one being the small demand after the armistice was signed, amounting to an almost complete suspension during the early part of the year 1919, and only about 55 per cent of the "oficinas" (works) were in operation during the second half of the year. The second cause of the small profits for the year 1919 was the fact that contracts had been made at a low price, 9s. per quintal, for their output for deliveries up to the end of March, 1920. (The Spanish quintal, which is in use in the nitrate industry of Chile, is equivalent to 101.4 lb.)

When the price began to go up toward the end of the year the producers did not share in the increase nor in the higher prices prevailing during the past three months of this year, the prices going as high as 16s. 1d. per quintal in April, and at the present time 16s. 3d. is asked by the brokers. The cost of production in the meantime had risen considerably, owing to strikes of the workmen and the stevedores in the ports of shipment, making the cost delivered alongside much higher than in September, 1919. This, of course, made a reduction in the profits of the companies producing the nitrate of soda.

COMPANIES IN GOOD CONDITION

However, at the present time the old contracts at the low price have practically all been completed and the new contracts will be made at prices over 15s. per quintal, possibly over 16s. per quintal, and the companies will therefore be in a better position than at any time since the armistice was signed to do a profitable business, and it is therefore not likely that they would care to sell out their plants at a time when the future for a prosperous business seems almost assured. Some of the smaller plants might sell out or merge with one of the larger companies.

The German nitrate companies are uncertain and it is reported that some are in financial difficulties and might have to be sold out.

Press telegrams dated from London report that the German nitrate company called "Augusta Victoria" has made some inquiries as to the possibility of the sale of its Chilean properties to an American syndicate. This is one of the largest German companies and has its office in Bremen.

The Acid Bessemer Process*

BY RICHARD S. MCCAFFERY†

THIS paper considers certain aspects of the acid bessemer process, particularly in its relations to the duplex process—that combination in which the pig iron is first desiliconized and decarburized in acid bessemer converters and then dephosphorized in basic open-hearth furnaces. The acid bessemer process employs an acid-lined converter and produces an acid slag. The blow is usually thought to eliminate the silicon and manganese as oxides and then to burn off the carbon as carbon monoxide. On account, however, of the relatively large amount of metallic iron present in the converter, compared with the relatively small amount of the impurities it is desired to oxidize, the first reaction in the converter probably is the formation of iron oxide, which dissolves in the bath and acts as an oxygen carrier for the silicon and carbon. As soon as iron oxide is dissolved throughout the bath, the oxidation of silicon commences; but in the early stages of the blow the mass law would indicate that iron oxide must form first, and this oxide probably increases up to some saturation point. The molten metal in the converter from the early stages of the blow right through to its completion remains basic, while the slag produced is siliceous. This fact is shown by the corrosion of the acid bottom and the tuyères, which is greatest at the tuyère orifice where oxidation is most active and where there is the most iron oxide.

ADVANTAGE OF BASIC TUYÈRE BLOCKS

Why does this acid bottom corrode? Because it is attacked by a base. The thought, therefore, suggests itself, why not make the bottoms of basic or neutral material? As the converter slag is acid, those parts of the converter coming in contact with the slag should be acid; but those parts of the converter that are in contact with the molten metal saturated with metallic oxides should be basic or neutral. Bessemer operators have for some time tacitly admitted this condition, for the blast pressures have steadily increased with the object of keeping the metal in suspension, and so preventing bottom corrosion; if the molten metal were not basic, it would not attack an acid bottom. In addition, the tuyères are bunched together at the middle of the bottom and a clear space is left around the outside of the bottom; if tuyères are placed too near the side walls, the wall corrosion increases. If the increase of blast pressure in bessemer converters was for the sole purpose of hastening the blow by getting more oxygen into the converter in the same time, the number of tuyères might have been increased, thus increasing the volume of air and decreasing the blast pressure. It is not desirable, though, to follow this procedure, because the additional tuyères can be provided only by placing them near the side walls, which results in increased lining costs.

In a normal blow, the carbon stage begins after the oxidation of the silicon, the carbon burning largely to carbon monoxide; it thus does not generate sufficient

heat to raise the temperature of the bath during the latter part of the blow; the great rise in bath temperature takes place in the early stage when the silicon is burning. Many converters, though, particularly those of larger capacity, do not blow a charge in this way; they show a temperature rise during the latter part of the blow, the carbon being burned to dioxide instead of to monoxide, with the resulting liberation of 97,000 calories instead of 29,000 calories. As a matter of fact, many blows that are not initially of too high silicon content are finished at excessively high temperatures, in some cases running up to 1,800 deg. C. Although the bad effect of this practice is known and attempts are made to lower the final temperature by the addition of scrap to the converter or by the introduction of steam in the air blast, the best method of lowering this temperature, by burning the carbon to monoxide, which also decreases by one-half the power consumption during the carbon stage of the blow, is not used because it is necessary to keep the metal charge away from the converter bottom.

ECONOMY IN LOWER BLAST PRESSURES

By following the present practice the direct bottom expense may be reduced seemingly, by employing a high blast pressure, but the power cost is greatly increased and the temperature of the finished blown metal is very high; or if the finishing temperature is kept down to the proper point, there is the extra expense of scrapping or of steaming. It does not seem right to charge scrap in a process that has as one of its principal objects the production of scrap, or to expend energy for excess air in order to turn carbon to dioxide when the extra amount of air will be furnished by the atmosphere at the converter mouth. By this plan a vicious cycle is in operation: more energy is employed for blowing in more air, which produces more heat, which requires more energy, in the form of steam, to lower the temperature. With the use of basic or neutral bottoms, blast pressure may be reduced and the tuyère area increased because the basic charge will not corrode bottoms of this character. The actual blowing time then can be materially shortened, no scrapping or steaming is necessary, and a colder blown metal is produced.

The author has already pointed out the possibilities of decreasing the time of blow and decreasing the power consumption with the use of a greater number of tuyères and lower blast pressure; and Table I summarizes the data obtained in a test of a 23-tuyère bottom compared with a bottom designed by the writer containing 35 tuyères.

TABLE I. RESULTS OBTAINED BY INCREASING NUMBER OF TUYÈRES AND DECREASING BLAST PRESSURE

IMPORTANCE OF TEMPERATURE IN DUPLEXING

In the open-hearth stage of the duplex process, the temperature of the open-hearth bath is an important factor if the dephosphorizing operation is to be successfully carried out, also the temperature of the blow metal passing from the converters to the open hearth

†Professor of Metallurgy, University of Wisconsin.

The use of basic and neutral material for making the bottoms in acid-process steel converters is protected by U. S. Patent No. 1,328,655, issued April 27, 1920.

¹Iron Age, (1919), vol. 103, p. 626.

is of great importance. To obtain maximum capacity in the open hearth, just as soon as it is ready for the blow metal, the blow metal from the converter should be ready to be poured in; and when the kicker charge is introduced, the bath should be at the proper temperature for the reactions to take place in the proper order. It should not be necessary to raise or lower the temperature of the heat very much. If the temperature of the molten bath in the open hearth is too high, the carbon is burned off first and after nearly all of it has been eliminated the phosphorus is oxidized and slagged. If the bath temperature is correct, the phosphorus reaction takes place first and the heat is finally worked down to the desired carbon content. Carbon is much more active in taking oxygen out of the molten metal than is phosphorus, with the result that when the process is carried out at the proper temperature and the heat is finished on carbon, the steel produced is much less likely to contain oxygen than when the heat is finished on phosphorus. The importance of this point, with respect to the bessemer stage, is that under certain conditions, already pointed out, the converters may furnish blow metal at an excessively high temperature which may be poured into an open hearth that, for various reasons, may be at a higher temperature than normal, with the result that the order of reactions in the open hearth is reversed and the open-hearth product may contain oxygen.

When running down at the end on phosphorus in this way, there is a twofold danger. If oxygen additions are made for the purpose of getting out the phosphorus, there is a chance that the steel will carry oxygen, although it may be thoroughly dephosphorized; whereas if there is not sufficient oxygen-carrying material charged to eliminate the phosphorus, the metal may not contain oxygen, but it will not be dephosphorized. The alternatives then, when an open-hearth bath is finished on phosphorus, are that the metal either will be oxidized or the phosphorus will not be eliminated, whereas, if the order of reaction were changed and the phosphorus were removed first and the carbon taken out at the end, the carbon would protect the metal from oxidation after dephosphorization and good steel would be produced.

It is not claimed that this happens in every open-hearth heat, but it does happen in some. This sequence of happenings can be avoided and the possibility of oxygen-carrying steel being made will be cut down to a minimum if excessive blast pressures are avoided. This can only be done economically, in the opinion of the writer, if basic or neutral converter bottoms are employed. The use of these bottoms will avoid the high blast pressures and cut down the power cost by burning the carbon to monoxide. In accomplishing both of these, the production of overheated blown metal will be minimized and the possibility of producing oxidized steel will be very slight.

Asbestos Can Be Fine Spun

The earliest use of asbestos was for spinning and weaving, to make incombustible thread and yarn rope and cloth, and this has continued to be the most important use of asbestos ever since the days of the Greeks and Romans. Only the best grades can be used for this purpose, according to J. S. Diller, of the United States Geological Survey, Department of the Interior. Thread can now be spun so fine that it will run about 32,000 feet to the pound.

Use of Domestic Graphite in Crucibles

The Bureau of Mines reports in Bulletin 112, "Mining and Preparing Domestic Graphite for Crucible Use," that prior to 1915 practically all of the graphite and clay used in the manufacture of crucibles in the United States was imported. The graphite came chiefly from Ceylon, Madagascar, and Korea, while the clay was obtained principally from Klingenburg, Bavaria. Domestic graphite was for the most part used in the manufacture of paint, lubricants, foundry facings, etc.

As a result of cessation of imports of clay, due to the war, manufacturers in this country sought a native product to replace it, and a substitute was soon found which compared very favorably with the foreign article.

The use of domestic flake graphite, however, in proportion to more than 25 per cent mixed with imported graphite was not very successful.

However, the domestic graphite mining and milling industry expanded rapidly under pressure of war conditions, being aided by a request of the War Trade Board on August 10, 1918, that crucibles manufactured during the balance of 1918 should contain 20 per cent domestic flake and 25 per cent thereafter. At the end of the war there were 39 graphite plants in Alabama, 3 in New York, 5 in Pennsylvania and 3 in Texas.

The graphite investigation of the Bureau of Mines covered three phases: (1) Field examination of the graphite deposits in the states mentioned, and a study of the methods used in mining and preparing graphite for market. (2) Experimental work on the concentrating and refining of crucible graphite to improve the quality of the product and lessen waste. (3) Experimental work in crucible manufacture to determine the property of domestic flake and the maximum proportion that might be used without impairing the quality of the crucible.

The present importance of these investigations lies in the fact that the domestic industry, if it is to survive the competition of imported graphite, which can be mined and prepared more cheaply than domestic graphite, must rely on improved and more efficient methods of producing and preparing graphite. Also for full extension of the market to domestic producers, crucibles made entirely of domestic or nearly all domestic flake in combination with domestic clays should be developed.

Peat Production in Norway

Smolen Island, near Kristiansund, N., is a flat spot of land possessed of immense areas of peat bog. It is doubtful whether there is anywhere a better location for the production of peat in large quantities.

Some time ago a company was organized under the name of "Smolen Co." It owns large areas on the island, and has a modern plant with six large machines for preparing the peat for market, after which it is transported on tracks down to the company's wharves.

It is expected that 30,000 tons will be produced this year, increasing till production reaches 50,000 tons a year.

Even a coasting steamship company serving the local trade in that vicinity has used peat for its steamers, enabling them to keep up their routes to full extent, while other local lines had to reduce their sailings because of the coal situation.

The "Smolen Co." intends also in the near future to extend its business to the manufacture of coal briquets for use by steamers and factories.

Properties and Constitution of Glues and Gelatines—III

Relations Between Physical Properties and Chemical Constitution and Influence of Size of Molecule Upon Physical Constants—Proximate Constitution and Jell Strength—Study of Magnesium Sulphate Precipitation of Larger Protein Particles*

BY ROBERT H. BOGUE, PH. D.

ATTEMPTS are constantly being made to correlate the physical characteristics of substances with their composition, their constitution and their molecular structure, and, by developing specific relations between these, to thereby account for and explain the particular behavior of the substances in question.

Since but little effort has been made by other investigators toward the establishment of a relationship between the viscosity and jell strength of glues and gelatines and their constitution, it seemed desirable that a study be made with this end in view. This investigation was accordingly initiated, and a clear-cut relationship has been established.

PROXIMATE ANALYSIS

Several sets of experiments have been performed to show whether or not any relation exists between the proximate constitution of glues, and their jell strength and viscosities. These experiments covered glues of every grade and variety. They were analyzed for water, ash, organic matter and nitrogen.

A study of the results obtained from these determinations, shows that:

The water content of the air dry glues varies directly as the jell strength.

The total organic matter varies inversely as the jell strength.

There seems to be no consistent variation with jell strength in the case of ash or nitrogen.

The consistent variation with respect to water signifies only that the water-retaining capacity of glues runs parallel to the jell strength, and that whatever factor controls the one controls likewise the other.

Examples of the data obtained are given in Tables XXVI and XXVII.

NITROGENOUS ANALYSIS—PRELIMINARY TESTS

Study of Magnesium Sulphate Precipitation. In the study of proteins which have been to a greater or a lesser extent hydrolyzed, it has been customary to distinguish in these products of hydrolysis four distinct groups of substances. These are known as proteins, proteoses, peptones and amino acids. There are many sub-groups which have been designated positions in the series but they are not separated in this study.

The proteins are designated as those groups which are precipitated by half saturated solutions of ammonium, zinc or magnesium sulphate. The proteoses are those groups which are precipitated between half and complete saturation. Peptones and amino acids are not precipitated at saturation of the above salts. The amino acids may be determined in this filtrate by the nitrous acid method of Van Slyke,¹ or by the formol-titration method of Sørensen,² and the peptones calculated.

Ammonium sulphate was not used in the precipitations, as it would involve a troublesome correction in the nitrogen determinations. Magnesium sulphate was used as being the less expensive of the remaining salts. The formol-titration method of Sørensen was used for the amino acid determinations.

To determine the most favorable conditions for precipitation and to study the errors in the process, two glues were treated by various methods as follows:

TABLE XXVIII. STUDY OF NITROGENOUS SEPARATIONS

	No. 8	No. 9

*For Parts I and II, see CHEM. & MET. ENG., vol. 23, Nos. 1 and 2, July 7 and 14, 1920, pp. 5 and 61.

¹Trotman and Hackford [J. Soc. Chem. Ind., vol. 23 (1904), p. 1073] developed a relationship between the "gelatines" precipitated in a saturated zinc sulphate solution and the "consistency" of the jelly, which is in agreement with one of the relations hereinafter described.

²Schryver, "Allen's Commercial Organic Analysis," vol. 8, pp. 467-495.

³Van Slyke, J. Biol. Chem., vol. 12 (1912), p. 275; and vol. 16 (1913-14), p. 121.

⁴Sørensen, Biochem. Z., vol. 7 (1907), p. 45, et seq. See also Schryver, loc. cit., p. 488.

A study of the relations expressed above led to the adoption of the following scheme in analysis.

Each sample weighed out and made up to such volume that 50 c.c. contains one gram.

A 50 c.c. aliquot used for total nitrogen.

A 50 c.c. aliquot saturated with magnesium sulphate for the estimation of protein plus proteose nitrogen.

A 50 c.c. aliquot treated with 50 c.c. saturated magnesium sulphate solution for estimation of protein nitrogen.

Proteose nitrogen estimated by difference between protein plus proteose nitrogen and protein nitrogen.

Amino nitrogen determined by Sørensen's method⁴ in filtrate from precipitation by saturated magnesium sulphate.

FIG. 14. EFFECT OF SULPHURIC ACID ON PROTEIN PRECIPITATION

Peptone estimated by difference between total nitrogen and the other three groups.

Effect of Temperature. That considerable variation in the uniformity of the magnesium sulphate precipitation might be due to variations in temperature was evident. This point was tested out carefully by precipitating a series of glues and allowing them to stand at different temperatures.

The data show that the solubility of the proteins varies directly as the temperatures, there being from 3 to 8 per cent more protein nitrogen thrown down at 17 deg. than at 25 deg. C.

TABLE XXIX. EFFECT OF TEMPERATURE ON PROTEIN PRECIPITATION

Grade II ₄ , 30 per cent saturated MgSO ₄ precipitations			
No.	Precipitated at 25 Deg. Filtered at 25 Deg.	Precipitated at 17 Deg. Filtered at 17 Deg.	Precipitated at 17 Deg. Filtered at 30 Deg.
1	41.9	50.1	41.3
2	44.8	52.0	46.0
3	50.9	57.7	49.7
4		58.3	50.3
5	55.5	58.7	51.7
6	56.2	59.4	52.2
7	53.7	56.2	50.9

From the above, it is evident that wherever comparisons are desired between the nitrogenous substances

precipitated from different glues, it becomes necessary to work under carefully controlled temperature conditions, or else run a complete set simultaneously. Otherwise wide variations may be expected. A temperature of 25 deg. C. was used in the following determinations as being the most convenient.

Effect of Varying Amounts of Sulphuric Acid. It was found that some acid must be added to the nitrogenous solution or to the magnesium sulphate in order that precipitation should result on the mixing of the two solutions. S. B. Schryver⁵ has recommended the addition of 2 c.c. of dilute (1-4) sulphuric acid to each 100 c.c. of above mixed solutions. This point was tested by the addition to a glue of varying amounts of dilute sulphuric acid, from 0 to 10 c.c. of a 1-4 solution, precipitation being brought about by a 30 and 35 per cent saturated magnesium sulphate solution.

It will be seen that in both instances the maximum precipitation was produced by the addition of 2 c.c. of 1-4 solution to 100 c.c. of the precipitating mixture. Both above and below this amount the nitrogen thrown down decreases. This amount was therefore used in all determinations.

The data are given in Table XXX, and are expressed graphically in Fig. 14.

TABLE XXX. EFFECT OF SULPHURIC ACID ON PROTEIN PRECIPITATION

Glue H ₄ , 1 g. glue. Total volume solution, 100 c.c.

0 5	41.3	57.9	
1 0	40.3	57.3	
2 0	39.3	57.0	
5 0	32.4		
10 0	17.5		

Study of the Formaldehyde Titration. The usual directions for the formaldehyde titration⁶ specify that the formaldehyde and the solution containing the amino acids should both be made faintly pink to phenolphthalein before mixing. It was found, however, that if these instructions were followed in our case, the solution resulting from the mixing would become intensely red, making a determination impossible. The control of saturated magnesium sulphate responded similarly. The process was therefore modified as follows: the amino acid solutions in saturated magnesium sulphate, and the control, were made faintly pink to phenolphthalein. The formaldehyde was treated with sodium hydroxide until, on adding 25 c.c. of it to 100 c.c. of the control, the intensity of the original pink remained unchanged. A drop more of the base would cause an intensifying of the color; a drop less a decrease or removal of color. The amino acid solutions were then treated similarly and titrated back to a uniform, rather deep, red with barium hydroxide in N/5 concentration.

The relative accuracy of the formaldehyde titration method with different concentrations of amino acids was studied as follows: Two g. each of two glues were hydrolyzed with hydrochloric acid for 24 hr. These were filtered, clarified with a silver chloride precipitation, refiltered, made up to 200 c.c. and aliquots of 50, 25, 10, 5 and 1 c.c. removed in duplicate and titrated for amino acid content.

At the higher concentrations the color of the solution

⁴Loc. cit.

⁵Loc. cit., p. 484.

⁶Loc. cit., p. 488.

interfered with the accuracy of the end point, and at very low concentrations the errors of manipulation became large in comparison with the weight of sample. The intermediate concentrations check very well. It was therefore decided best that the entire filtrate from the

TABLE XXXI. EFFECT OF CONCENTRATION ON FORMALDEHYDE TITRATION

Volume, c.c.	Weight, g.	No. 8		No. 9	
		Ba(OH) ₂ c.c.	Per Cent N	Ba(OH) ₂ c.c.	Per Cent N

1	0.01	0.25	7.3	0.27	7.8

precipitation by saturated magnesium sulphate be used in all amino acid determinations. The data are given in Table XXXI.

RELATIONS OF NITROGENOUS CONSTITUTION TO JELL STRENGTH

Having found no fundamental relation to exist between the proximate constituents of glues and their jell strength, it was decided to separate their nitrogenous constituents by the previously described magnesium sulphate precipitation method. Accordingly, a large number of glues and gelatines were analyzed for their protein, proteose, peptone and amino acid content. Those analyzed included all of the standard grade

FIG. 15. RELATION BETWEEN NITROGENOUS CONSTITUENTS AND JELL STRENGTH, HIDE GLUES

glues, Russian isinglass from sturgeon sounds, an edible gelatine, fish glue, peptone and several other series of glues.

The results of all of these analyses show a most clear-cut relation to exist between these nitrogenous constituents and the jell strength, which may be summarized as follows:

The protein nitrogen varies directly as the jell strength.

The proteose and peptone nitrogen vary inversely as the jell strength.

The amino acid nitrogen shows a slight tendency to vary inversely as the jell strength.

The amino acid nitrogen is higher in bone glues than in hide glues and fleshings.

FIG. 16. RELATION BETWEEN NITROGENOUS CONSTITUENTS AND JELL STRENGTH, BONE GLUES

The jell strength of a glue is therefore determined by and is probably absolutely dependent upon the ratio of its protein nitrogen to its products of hydrolysis, chief among which is the proteose nitrogen.

The data of this set of determinations are given in Table XXXII. The figures represent the percentage of the total nitrogen which is precipitated. The graphical representations of the results are shown in Figs. 15 and 16.

TABLE XXXII. RELATION BETWEEN NITROGENOUS CONSTITUENTS AND JELL STRENGTH

	Grade	Protein N	Proteose N	Peptone N	Amino Acid N
Hide glues and fleshings	H1	92.2	6.3	1.1	0.4
	H2	90.4	7.0	2.0	0.6
	H3	86.2	12.0	1.4	0.4
	H4	84.6	12.4	2.6	0.4
	H5	78.7	16.0	4.5	0.8
	H6	77.6	17.0	4.7	0.7

Fish glue	B9	33.4	42.3	21.9	2.4
Pressure tankage	B9	34.3	46.4	16.3	3.0
Peptone	B9	0.0	33.2	48.5	18.3

In order to note if the variation in protein content as determined by precipitation in a half-saturated solution of magnesium sulphate would persist if the effect of viscosity were cancelled, a series of five glues of equal viscosity but varying jell strength were analyzed for protein nitrogen.

It was found that the protein nitrogen varied directly as the jell strength, regardless of the uniformity in viscosity, as is shown in Table XXXIII.

TABLE XXXIII. RELATION BETWEEN PROTEIN NITROGEN AND JELL STRENGTH

Jell Strength	Viscosity	Protein
63	46.2	83.5
64	45.8	84.2
66	46.0	84.9
68	45.8	85.3
70	46.2	85.5

RELATION OF NITROGENOUS CONSTITUTION TO VISCOSITY

Several series of glues were studied to ascertain if any relation existed between the nitrogenous constitution of glue and viscosity. Each series consisted of several glues of uniform jell strength and varying viscosities.

Although the greatest care was used in the elimination of sources of error, the results obtained do not show

any consistent relation to exist between these nitrogenous constituents and viscosity.

SUMMARY UPON CHEMICAL CONSTITUTION

There appears to be no relation between the proximate constitution of glues and their jell strength and viscosities, except that the water content of the air dry glue is proportional to the jell strength. This means that the water-retaining capacity of glues and gelatines is controlled by the same factors as determine the jell strength, which, as has been shown, is the ratio of protein to its products of hydrolysis.

The jell strength varies directly as the protein nitrogen, and indirectly as the proteose and peptone nitrogen in all glues and gelatines.

The amino acid nitrogen is greater in bone than in hide glues, and tends slightly to increase with decrease in jell strength.

If the jell strength remain constant, the variations in viscosity are not traceable to variations in the ratio of the protein to its products of hydrolysis; proteose, peptone, and amino acids.

INFLUENCE OF SIZE OF MOLECULE UPON PHYSICAL CONSTANTS

It has been noted in a previous paper² that viscosity and jell strength are functions of the melting point.

²See Part II.

Assuming that the several grades of glues are essentially of the same original composition, differing only in the extent of the hydrolysis which they have undergone, it seems reasonable to expect that the melting point will be determined primarily by:

The resultant of the melting points of the several nitrogenous constituents, protein, proteose, peptone, and amino acids.

The resultant of the melting points of the variously sized molecules which constitute the several products of hydrolysis.

As to the first of these, we know that the protein gelatin possesses a higher melting point than its products of hydrolysis. We should therefore expect that in glues the melting point would vary directly as the grade (since we have found that "grade" or jell strength is a function of the protein content).

This we know to be the case, since, in general, the viscosities vary as the jell strength³ and viscosity is a function of the melting point⁴.

With regard to the second of the possible causes for variation in melting point, it seemed probable that within any one group as protein, or proteose, the molecules constituting that group might vary considerably in size. (The ultimate molecule is referred to here, and not the aggregate of molecules going to make up a colloidal complex, which is even more subject to change. The writer differentiates these conditions by maintaining the molecule to be a group which may not be subdivided except by chemical processes, as of hydrolysis, whereas the colloidal complex is established probably by electrical phenomena and the processes of chemical condensation or hydrolysis are not involved.) This seems especially plausible since the line of division between the several groups is a very arbitrary one, depending solely upon their relative solubilities in salt solutions. So, for example, the "protein" consists of all those molecules which are sufficiently large to be insoluble in and precipitated by a half saturated solution of magnesium sulphate⁵. But it may be presumed that these large molecules may vary greatly in size. The protein fraction of one glue may have a large proportion of its molecules of great size, and another glue of size just sufficiently large to be precipitated. In such a case, especially when the protein fraction includes three-quarters or more of the total organic material of the glue⁶, such variation in the size of its constituent molecules would certainly be expected to reveal itself by like variations in melting point and hence in viscosity.

This hypothesis was tested by subjecting a number of glues of uniform jell strength and varying viscosities to precipitation by less than half-saturated solutions of magnesium sulphate. It was assumed that as the strength of the salt solution was decreased, the minimum size of those protein molecules which were thrown down would be progressively raised, so with the lowest concentration of salt only the largest molecules would come down. Magnesium sulphate concentrations of from 50.0 per cent down to 24.0 per cent of saturation were used. Below 24.0 per cent, the precipitate was so finely divided and slimy as to render filtration practically impossible. The data of these determinations are given in Table XXXV.

9	H ₄	65½	50.0	86.0	66.9	52.8	44.0
10	H ₄	65½	50.2	85.2	66.4	52.1	48.7
Series 4									
11	H ₄ +	66	47.4	83.0	63.1	47.7	42.5
12	H ₄ +	66	48.6	87.0	71.8	49.7	46.1
13	H ₄ +	66	48.8	85.2	71.6	50.3	46.1
14	H ₄ +	66	49.2	86.2	64.3	52.2	46.8
15	H ₄ +	66	49.6	85.2	68.0	51.7	49.0
16	H ₄ +	66	49.8	83.2	65.5	52.7	49.4

An examination of the data will show that at the low concentration of 28.0 per cent to 30.0 per cent of saturated magnesium sulphate, except in one instance where it was necessary to go as low as 24.0 per cent, the nitrogen thrown down in the several precipitates varies directly as the viscosity, the jell strength being

FIG. 17. THE RELATION OF NITROGEN PRECIPITATED BY 28 PER CENT SATURATED $MgSO_4$ TO VISCOSITY

uniform. This means that if the jell strength be constant the viscosity will vary as the size of the protein molecules.

The results from the precipitation by 28.0 per cent saturated magnesium sulphate solution are expressed graphically in Fig. 17.

It had been observed that if the viscosity were constant the jell strength would also vary as the melting point. To further study the reason for this, a number of glues of uniform viscosity and varying jell strength

were treated with 50.0 per cent and 30.0 per cent saturated magnesium sulphate and the precipitates Kjeldahled as before for nitrogen. The results are given in Table XXXVI.

TABLE XXXVI. RELATION OF SIZE OF MOLECULE TO JELL STRENGTH

No.	Jell	Viscosity	50 per Cent	30 per Cent
1	63	46.2	83.5	45.0
2	64	45.8	84.2	46.2
3	66	46.0	84.9	46.7
4	68	45.8	85.3	55.1
5	70	46.2	85.5	57.4

It will be seen that at both 50.0 per cent and 30.0 per cent magnesium sulphate saturations, the nitrogen thrown down in the several precipitates varies directly as the jell strength, the viscosities being practically constant. This means then that at constant viscosity the jell strength will vary as the size of the protein molecule, as well as with the total amount of protein.

It seems, therefore, in the light of this set of experiments that:

The melting point, and therefore the viscosity, of a glue is determined normally by the balance between its protein content and that of its hydrolyzed products, but

At any given uniform jell strength, the melting point and viscosity will depend upon the ratio of large to small sized molecules within the protein group.

The positiveness of the above results makes it appear improbable that variations in size of molecule within the other groups would be of sufficient influence to seriously modify the effects noted above. This is to be expected, for

The amounts of the other groups present in normal glues is nearly always small in comparison with the protein group, and

As the size of the molecules decreases, their effect on melting point and viscosity likewise diminishes, so that a much larger amount would be necessary to produce an equivalent effect.

(Part IV will be published in a subsequent issue.)

Vegetable-Oil Industry in Japan

According to the latest available statistics, the exports of various vegetable oils from Japan for the first nine months of 1919, compared with those of the whole of 1918, are as follows:

Kind of Oil	January-September, 1919		Total, 1918		Exports to America, 1918	
	I.b.	Value	I.b.	Value	I.b.	Value
Cocunut...	21,134,967	\$2,757,046	53,950,258	\$6,846,732	49,244,641	\$6,216,924
Soya bean...	3,170,323	348,115	6,570,957	754,800	5,225,784	601,126
Cottonseed...	947,443	141,307	2,446,397	301,175	1,189,211	138,614
Camphor...	666,967	59,198	1,827,825	133,633	1,057,307	70,577
Peppermint...	438,179	485,140	286,180	274,033	8,368	6,450

The center of the oil-crushing industry is Kobe. The majority of the mills employ the pressure method of oil extraction, using one of three types of hydraulic-pressure machinery: (1) The round-bed type, with a bed about 18 in. in diameter, used for beans and rape-seed; (2) the oblong, flat-bed type, about 30 x 14 in., used for pressing copra; and (3) the bowl type, in which a stone bowl is pressed into a mass of seed pulp held by iron hoops, used in second and third pressings of peanuts and beans. One mill is reported as using an American rotary-type screw expressor, and a few have adopted the benzine-extractor process. Nearly all the mills can crush any kind of vegetable-oil seeds by a slight adjusting of the machinery.

²²See p. 107.

The Application of Copper-Refining Practice to Other Fields

BY LAWRENCE ADDICKS

ELECTROLYTIC refining has attained its chief application and highest development in the metallurgy of copper. The very dynamo, the invention of which created the large-scale demand for high-conductivity copper, gave the means of producing it by electro-deposition, and electrolytic refining on a commercial scale was one of the first electrical industries to be developed, while it remains today by far the largest application of the electrolysis of an aqueous electrolyte.

The experience gained in this field has found wide application in the refining of other metals, such as silver, gold, lead, bismuth, tin, nickel, iron and zinc, and in the recovery direct from the ore by leaching of copper, silver, gold and zinc. The successful application of electrolysis to these different fields requires a rebalancing of the various factors discussed in previous articles by the author, the relative values of which are often greatly altered by a change of metal. In any given case we must take into account (1) competition from other processes, (2) acid radical to be employed, (3) temperature of electrolyte, (4) character of deposit, (5) resolution at the cathode, and (6) depolarization at the anode.

COMPETITION

Electrolytic copper refining has no effective competitor in its own field. Fire refining makes a low conductivity product unless furnished with very pure raw material such as selected Lake "mineral," and the various selective methods of reverberatory treatment yield but a partial recovery of gold and silver.

In the leaching field electrolysis has to meet several competitive methods of reduction, notably precipitation upon iron. While a free acid equivalent by electrolyzing is returned to the cycle, there are usually serious handicaps imposed by large quantities of impurities which cause various troubles in the cells and which progressively accumulate unless some outlet is provided. Even where electrolysis is indicated, therefore, an iron precipitation plant is usually required as an adjunct, from 10 to 30 per cent of the copper being recovered as cement.

Electrolytic silver has to compete with the older sulphuric acid method of parting. The latter is easy to operate and ties up less silver, but it will not make a product so low in gold as the electrolytic. It is still indicated, however, for small plants or for those which are used spasmodically.

In the case of gold refining the question is almost wholly dependent upon the amount of platinum and associated metals present. If the original gold is free from this metal group, there is no object in tying up the gold several days for electrolysis and further increasing the opportunities for theft. When but very small quantities of platinum and palladium are present, they may be satisfactorily collected by wet methods instead of by electrolysis at about equal expense. When the quantities are larger electrolysis is indicated.

Electrolytic lead has to compete with the very efficient Parkes process of refining. When all factors are considered, the justification for electrolysis appears to rest almost entirely upon the quantity of bismuth present in the bullion to be treated. This objectionable

impurity is not satisfactorily removed by the Parkes process and special treatments such as Pattisonizing are expensive, while the electrolytic method readily separates the bismuth from the lead and converts it into a marketable byproduct.

Nickel, iron and zinc may be readily refined by electrolysis, but in ordinary times the value of the refined product, except in a very limited quantity, is not sufficiently above that of the crude to pay for the refining. Tin offers a special field for impure ores which are difficult to handle by fire processes.

In leaching, both nickel and zinc have strong competition from chemical and pyrometallurgical processes and this whole field is still in a state of flux.

In general, we can say that electrolysis enjoys no such absolute monopoly in other fields as it does in copper refining and that each proposed application must, therefore, receive full consideration upon its merits.

ACID RADICAL

While several salts of copper are suitable for electrolytic treatment, the sulphate possesses so many practical advantages that it is universally employed. The first requirement for an electrolyte is that the salt of the metal employed shall be readily soluble. The second is that the material which it is desired to collect in the slime shall be insoluble in it. The third is that the cathode should not be redissolved by the electrolyte. Copper sulphate is a readily soluble salt and copper; gold and silver are all practically unattacked by dilute sulphuric acid.

When electrolyzing silver a nitrate electrolyte is employed, as silver sulphate is not a readily soluble salt. The amount of free acid carried is necessarily low, as nitric acid is expensive and decomposes under the conditions of electrolysis. Copper concentrates in the electrolyte and is removed by withdrawals, while gold remains unattacked in the slimes.

In gold refining a chloride electrolyte is employed. Gold chloride is a soluble salt, platinum concentrates in the electrolyte, and although silver, being less noble than gold, dissolves at the anode, after saturation it precipitates as a secondary slime of insoluble chloride.

For lead, chloride and acetate were first tried, but not until Betts developed the fluosilicate electrolyte was the electrolytic refining of lead made a commercial success.

It will, therefore, be appreciated that an entirely new set of chemical conditions as regards behavior of impurities, etc., is encountered with every metal refined.

TEMPERATURE OF ELECTROLYTE

While it is customary to heat copper electrolytes externally, quite opposite conditions obtain in the case of silver, lead and zinc. Nitric and hydrofluosilicic acid show increasing decomposition losses with rise in temperature, asphalted tanks do not stand hot liquors and zinc resolution losses must be limited. In the case of silver, the current may have to be limited to control the temperature; for lead, extraneous heating is abandoned, and with zinc, where the specific resistance of the electrolyte is high, cooling systems carrying circulating water must be employed.

CHARACTER OF DEPOSIT

At moderate densities copper readily gives a good adherent deposit. The same may be said of gold. Silver gives normally a loose crystalline deposit. Nickel is

nodular, while lead and zinc tree very badly. By the proper use of addition agents all of these deposits may be made smooth and coherent. In fact it was not until the value of addition agents was more or less understood that lead could be handled at all.

In the early copper plants a great deal of trouble was had in getting good starting sheets, and it was thought that the addition of ammonium sulphate was a help, the use of double salts being common practice in various electroplating prescriptions. Then the beneficial effect of the presence of wood strips on the edges of the starting blanks led to the introduction of wood tea made from shavings, yielding a complex organic addition agent. Finally the remarkable results following the addition of gelatine were worked out. The irregularities of early practice were due to overdosing and a failure to appreciate the fleeting effect of a single dose. Today a few pounds of common glue dissolved in water and added regularly throughout the twenty-four hours, together with a can of ordinary engine oil, will control the deposit in the tank house of a great copper refinery, permitting the use of higher densities, closer spacing and greater cathode age.

For silver, while adherent deposits can be made in similar fashion, it is customary to collect the silver crystals as such, either brushed to the floor of the tank from vertical cathodes by mechanical scrapers as in the Moebius system or shoveled by hand from the horizontal carbon cathode of the Thum cell. These crystals are readily washed free of electrolyte and fed to retorts for melting.

Lead may be beautifully controlled by addition agents. The exact amount to be added varies from time to time and is determined by experiment and careful watching of the fresh deposit on special strips hung for the purpose.

Zinc is generally plated in coherent form on an aluminum cathode, from which it is peeled every forty-eight hours. There is no reason why zinc starting sheets could not be used as in the case of copper, and in some ways the avoidance of a zinc-aluminum couple would be of advantage. In the development of electrolytic zinc practice, however, there has been great difficulty in controlling resolution at the cathode, and the great advantage of using aluminum sheets lies in the fact that strong corrosion can do no more than leave the starting sheets bare, whereas were they of zinc they might be completely eaten through, causing collapse, open circuits, general demoralization and shut-down of the plant.

RESOLUTION AT CATHODE

The cathode is never absolutely insoluble in the electrolyte used and a small amount of reoxidation is always in process. In the case of copper with normal electrolytes it is a minor matter—perhaps 2 per cent. Should we allow an accumulation to take place of salts of manganese, iron or any other metal capable of alternate oxidation and reduction at anode and cathode with change of valence, a very serious condition may arise.

In these days copper anodes are so highly refined that the amount of iron contained in the electrolyte is quite negligible, but when electrolyzing liquors arising from the leaching of ore a very different situation exists. Such liquors commonly contain large quantities of ferrous sulphate and a certain proportion of ferric sulphate. Oxidation at the anode tends to increase the latter at the expense of the former. (See Addicks, *Trans. Am. Electroch. Soc.*, vol. 28, p. 87.) Experiments show

that 0.25 per cent of iron as ferric sulphate in an electrolyte sufficiently agitated will corrode cathode copper at a rate which will require a current corresponding to about 8 amp. per sq.ft. merely to replace the loss. The proper control of ferric sulphate is, therefore, the key to success in electrolyzing copper leaching liquors.

Another interesting example of resolution is in the case of zinc—in fact this is the controlling factor in zinc electrolysis. In the electrolysis of zinc sulphate using an insoluble anode the content of free sulphuric acid gradually increases and unless the cathode is absolutely pure zinc resolution is very active. Perfectly pure zinc is so nearly insoluble in sulphuric acid that it is quite difficult to get it in solution for analysis. But if a nodule of cathode zinc is immersed in dilute sulphuric acid in a test and the nearest trace of almost any impurity is added, a vigorous evolution of hydrogen will start at once. This is probably due to galvanic action, and the whole secret of successful zinc electrolysis lies in the passivity of pure zinc in sulphuric acid. This calls for a degree of purity in the electrolyte which would be quite uncommercial were it not for the fact that zinc dust readily throws down most of the impurities to be dealt with after the liquor from the leaching tanks has been neutralized. The last traces of some difficult elements, such as arsenic, are removed by adsorption upon freshly made ferric hydrate.

DEPOLARIZATION AT THE ANODE

Anode efficiency plays a relatively small part in normal copper refining; the proportion of impurities present in the anode is small and the useful anode efficiency very high. As soon as a complex or insoluble anode is substituted, however, the oxidizing effect of the current is in part or in whole employed in the solution of anode impurities, the oxidation of suitable salts in the electrolyte or in the decomposition of water with escape of oxygen as such. This introduces several new problems.

A moderate amount of an oxidizable impurity, such as nickel, in a copper anode gives the first and simplest case. The nickel and copper dissolve proportionately at the anode, sharing the current. At the cathode, however, only copper is deposited, so that the copper in the electrolyte is correspondingly depleted. About 2 per cent of the copper deposited is restored by purely chemical solution at the electrodes but beyond that figure soluble copper must be added by leaching shot or scale, and the accumulating nickel must be controlled by withdrawals to a byproduct plant.

The second difficulty arises when the quantity and nature of the impurity in anode causes segregation into two components one of which is more readily dissolved than the other. Then the anode disintegrates unevenly and a large amount of scrap has to be reworked.

A third and more serious condition is met with when the impurity is insoluble, such as lead or antimony, when the anode will become coated with a non-conducting slime. The voltage will then rise until some free oxygen is generated from the moisture underneath. This in turn will burst through the coating and the anode will act normally for a few seconds, when the coating will again form. A voltmeter connected across such a tank will show a wildly fluctuating needle, and this condition, known colloquially as "crazy tanks," is fatal to good refining, entailing as it does excessive gold and silver losses in the cathode, high power cost and a heavy expense for purifying electrolyte. The remedy lies in

properly refining the crude material before casting the anodes.

Finally, we have the extreme case where the anode is by intent insoluble, as where copper is being recovered from leaching liquor. Where no depolarizer is employed, the voltage must of course be sufficiently high to decompose water, and free oxygen is given off at the anode. When the liquor is virtually free from chlorides and nitrates, antimonial lead is generally used as the anode material; when electrolyzing zinc, however, pure lead is required in order not to poison the cathode with specks of antimony. When the liquor is corrosive, either magnetite or one of the ferro-alloys, generally ferrosilicon, is employed. None of these anode materials is wholly free from oxygen attack. Lead peroxidizes and sulphatizes and the iron alloys slowly dissolve, so that a certain replacement charge must be reckoned with.

Where an efficient depolarizer is employed, any of the materials mentioned above or carbon may be employed. Graphite offers peculiar advantages in that 100 per cent of efficiency of oxidation of ferrous sulphate or similar depolarizer is readily obtained by its use. Lead does not give equal results. On the other hand carbon itself will oxidize and disintegrate if not fully protected by the depolarizer. This whole question of a cyclic oxidization at the anode with subsequent reduction at the ore contact is yet in but partially developed form, most of the theoretical advantages being generally offset in practice by the difficulties met with in handling impurities dissolved from the ore.

Use of Esparto in Paper Making

During the European war the scarcity of paper pulp in the Spanish market, caused by the difficulty in securing supplies from the sources formerly relied upon, especially the countries bordering upon the Baltic coast, caused Spanish paper makers to consider the use of esparto to supplement the import supply. Esparto grows throughout extensive districts in the south of Spain, and a poorer quality is found on large areas of poor and sandy lands in Algiers and Tunis. Esparto fiber has been used for centuries in Spain, and the manufacture of matting, baskets and cordage exclusively of esparto dates from the time of the Moorish occupation.

EARLY EXPERIMENTS IN THE USE OF ESPARTO

Esparto was used in paper making in Great Britain as early as 1857. The industry met decided success in Scotland and a few years later the manufacture was started in the south of France, the raw materials being obtained from Algiers and Tunis, but it has never reached a prosperous basis in the republic, due to the inability to compete with the local straw papers. The industry in Spain in the regions bordering on the Mediterranean coast dates from 1869.

The greatest development of the esparto industry is still found in Great Britain, where the fiber has been used for making fine writing paper of great whiteness, and to some extent for newsprint, though for the latter purpose at the prices usually current other pulps are cheaper. Papers made from esparto are of great thickness compared to the weight and have the advantage of not shrinking or breaking when exposed to moisture. They have especial adaptability for the manufacture of lithographs. They are easily filled, absorb ink well, and

therefore are particularly adapted for fine printing, especially in color work. Esparto paper is highly esteemed for book making because of its texture and light weight.

INTEREST IN ESPARTO REVIVED PRIOR TO THE WAR

Shortly before the outbreak of the European war Spanish interest in esparto began to be revived. In 1910 the Papelera Española installed an experimental plant to use esparto pulp at Arrigorriaga, adopting the best methods which had been developed in Scotland. Because of the difficulties in securing pulp created by the war this plant was later enlarged and by 1917 a daily production of 2,000 kilos was reached and the following year a daily production of 4,000 kilos. Another enlargement of the plant was started in October, 1918, and in the first months of 1919 the daily consumption of esparto pulp reached 16,000 kilos, from which a yield of 8,000 kilos of paper was secured. Two other important plants were installed in 1916 at Aranguren and Renteria, each with a daily capacity of 10,000 kilos of esparto pulp.

In this way the Papelera Española has sought to reduce the necessity of importation of bleachable foreign pulps. During the war the chief preoccupation was to reach the maximum production in the shortest time. The company is now, however, making plans which will allow the placing of this industry on a permanent basis.

LIMITATIONS OF THE USE OF ESPARTO

Though esparto has exceptional qualities for certain uses in paper making, its fibers are not such as will allow its substitution for all the purposes for which wood pulp is used. The fibers are short and weak. The pulp is best used for filling, and is therefore employed largely in mixtures with longer and stronger fibers. Esparto is not suited for the manufacture of wrapping paper. It can, however, be used in larger proportions than has heretofore been the practice in most other grades, and thus make it possible for the Spanish manufacturers of paper to reduce their demands on the foreign market. In documentary papers and others in which great strength is needed not more than 20 per cent of esparto can be used. In writing papers, where light weight is desirable, esparto pulp can be used in large quantities.

For the cheaper grades, especially those in which incompletely bleached pulp is used, the higher price of esparto will, as a rule, make its substitution for bisulphite pulp impossible.

Denatured Alcohol Formula

The Treasury Department, United States Internal Revenue, has recently published Regulation No. 61 dealing with denatured alcohol. Of the various formulas given, No. 4, on page 97, of this bulletin will probably be the one most generally used, and is made up as follows: To every hundredth part by volume of ethyl alcohol should be added two and five-tenths part by volume of approved benzol, five-tenths part by volume of nitrobenzol, two-tenths part by volume of approved pine oil (steam distilled). The old No. 1 formula using wood alcohol has been suspended because so much of this material is being manufactured into formaldehyde, of which there is an acute shortage. The demand for formaldehyde is due to its use in treating grain for smut.

Some Commercial Heat Treatments for Alloy Steels for Structural Purposes*

A General Discussion of Principles of Heat Treatment, Having Especial Reference to a Nickel : Chromium Steel, the Effect of Time in Complex Heat Treatments, and the Development of Simple Heat Treatments From the Complex

By A. H. MILLER†

ALLOY steels both for tool and structural purposes have had an increasing application for a number of years. The present paper, for its limited purpose, will be confined to a discussion of steels for structural purposes, and will further limit itself to their heat treatment. It will apply directly to the two alloy steels which are probably used to a greater extent than all others combined—namely, nickel and nickel : chromium steels. It is to be borne in mind, however, that the statements to be made in regard to these two alloys are almost equally applicable to all of the structural alloy steels, provided temperature changes are made which correspond to the changes in the critical temperature of these alloys.

In speaking of heat treatments, a fundamental thought must always be held in mind, which is this: All fabricated steels have submitted to a heat treatment. The difference between steels known as heat treated and others commonly spoken of as untreated is merely that the treated steels have supposedly received a preconceived and carefully executed treatment, while the so-called untreated steels have received the variable and generally unknown treatment which is the result of casting, forging and cooling at an unknown and variable rate from the casting or forging temperature.

TIME AT THE HIGH HEAT

In the heat treatment of alloy steels, the three variables which must be controlled for a successful heat treatment are temperature, time and rate of cooling. The influence of mass on these three variables must never be neglected, and it must be borne in mind that an increase in mass may increase the treatment temperature, should increase the length of time held at temperature, and will inevitably alter the rate of cooling.

Too little attention is generally paid to the time element of the heat treatment, whereas it actually is of very great importance. To illustrate this, Figs. 1 to 7 inclusive show a series of photomicrographs of a nickel : chromium steel of composition C 0.35 to 0.40 per cent, Ni 3 per cent and Cr 1.50 per cent, showing the microstructure in a typical forged condition, and after annealing at a proper annealing heat for varying periods of time. It will be noted that this series gives the time held at the annealing temperature from zero (meaning that the piece was brought to temperature and the furnace was immediately shut down) to 10 hr. A study of the photomicrographs shows that the ferrite as contained in the cell outlines of the forged specimen was not dissolved and uniformly diffused until the piece had been held at the annealed temperature for $\frac{1}{2}$ hr. The last

photograph shows that there had been a slight growth of the austenite crystals between the time of completed uniform solution at $\frac{1}{2}$ hr. and the end of the run at 10 hr.

This series also shows that a new cell system may grow in steel simultaneously with the breaking up of the previously existent system. The pieces were all cut from the same bar, and were treated by placing all together in a furnace controlled by a thermocouple, withdrawing them one by one at the end of the specified time, plunging each immediately into a box of well aerated lime.

The reason that a considerable length of time is required to produce a uniform structure is probably as follows: After the steel is raised to a temperature above the critical temperature, the iron is in the gamma form, in which the ferrite is soluble. There is, however, a certain length of time required for this solution, and, more than that, a certain added length of time is necessary to allow the solution to become homogeneous; just as, in dissolving a lump of sugar in water, a certain length of time is required to complete the solution, and a certain further length of time for the water to become uniformly sweet. If the iron carbide should be dissolved in the gamma iron, but this solution not have had time to become homogeneous before it be recooled, ferrite will naturally separate out on cooling at the point where the greatest concentration existed in the solution.

COMPLEX HEAT TREATMENTS

The object of alloy steel heat treatment and indeed, with a very few exceptions, of all heat treatment is to produce a grain size as small as possible, with a degree of hardness suitable for the purposes intended, by the simplest possible means. Thus the ill-controlled and generally very poorly-forged structure must first be broken up, and a fine uniform structure established. In steels which are sensitive to heat treatment, of which the nickel and nickel : chromium steels are excellent examples, this object is best achieved in several steps, each of which is designed to break up the structure resulting from the previous step and to bring the material into a more nearly ideal condition.

If the forging conditions are bad, as is the case in most forging processes, especially that of drop forging, a treatment of numerous steps may be necessary. As an example of the most drastic I give the following:

First. Anneal from approximately 1,450 deg. F.

Second. Quench from 1,600 deg. F.

Third. Quench from 1,400 deg. F.

Fourth. Draw at 1,250 deg. F.

Fifth. Quench from 1,400 deg. F.

Sixth. Draw at such a temperature as will give the desired hardness.

*Read before the Washington Section, American Society of Mechanical Engineers, March 21, 1920.

†Bureau of Research, Midvale Steel & Ordnance Works.

This heat treatment is not of unheard length, as it is quite conceivably necessary in many cases. As a matter of fact, in manufacturing pieces which will not subsequently be forged by the purchaser, steel companies very frequently give all of the preliminary steps of this treatment to their regular product. It must be well understood, however, that this number of steps is necessary only to guard against lack of uniformity, due to one piece out of a great number having possibly been subject to a poor forging heat. If the forging temperature can be accurately regulated many of the steps in this treatment can be eliminated.

In much commercial work, with good forging practice, a simple anneal at 1,450 deg. followed by a quench just above the critical temperature and a draw will put the steel in excellent preliminary condition, at which point the steel can be machined to its final shape. If conditions are such that the steel must be extraordinarily hard (as in automobile gears) a final quench with a draw at about 400 to 600 deg. F. is given.

It must be borne in mind when laying out treatments that the time at which the steel is held at temperature during any treatment, whether it be an anneal or a quench, is of quite as great importance as the temperature. This is illustrated by photomicrographs of two pieces cut from the same bar as those previously shown, both of which were placed in the furnace together. One of these pieces (Fig. 8) was drawn from the furnace, and quenched immediately it had reached the quenching temperature (in this case 1,400 deg.). The other, Fig. 9, was allowed to remain in the furnace for $\frac{1}{2}$ hr. and was then quenched. It will be seen that the ferrite areas in the first case had been slightly or completely broken up, whereas in the second case they were very completely dissolved. Again Fig. 10 shows the fine grain resulting from a proper complex treatment.

These photomicrographs differ from a corresponding one in the first series of annealed samples in that there is shown no new grain growth within the old partially broken up system. This, of course, is due to the fact that

FIGS. 1 TO 7. EFFECT OF TIME AT NORMALIZING HEAT (1,450 DEG. F.) FOLLOWED BY SLOW COOLING

Heated to 1,400 deg. F. for 30 min., cooled slowly.
Heated to 1,150 deg. F. for 30 min., cooled slowly.
X 100.

in the second case the time element which is necessary for the separation of the ferrite during cooling was not sufficient.

PHYSICAL PROPERTIES POSSIBLE

As a result of a careful heat treatment of nickel : chromium steels Fig. 11 shows a series of curves, showing physical properties of a nickel : chromium steel resulting from proper preliminary treatment and varying drawing temperatures.

The type composition only is given on this curve, because it is a mean of the results of about twenty bars from several heats of slightly varying compositions. The nickel steels of the same approximate carbon content give results which are somewhat inferior to this nickel : chromium curve, whereas the results of another type of nickel : chromium steel, of 3½ per cent Ni, 1½ per cent Cr would be slightly superior to that just shown.

Starting from the extended heat treatment which we have just seen, the development of the cheapest and simplest treatment which will give good results is a matter of intelligently eliminating or altering steps of the ideal heat treatment as conditions permit. For instance, in a certain case which has come to my attention, one in which important drop forgings are manufactured from the grade of nickel : chromium steel shown on the curve, the actual treatment to which pieces were subjected is as follows: The pieces were forged under a drop hammer, and were dipped immediately afterward into a tank of oil which was situated close to the forge. The pieces were kept in this oil for about 4 min., being removed at a temperature between 700 and 900 deg. F. and then buried in ashes as a precaution against cracking. After this the pieces were subjected to a single quench at 1,400 deg. and were drawn at 1,200 deg. They were machined in this condition

and received no further treatment. The uniformly excellent results obtained (each of the pieces was separately tested) showed that this very simple treatment had been entirely effective. A little thought will show that the reason for this was that the drop forging was not excessively high, and that the growth of large cell outline was prevented by the quench after forging was completed. The single quench and draw were sufficient to completely refine the steel from the fair condition which was thus produced.

There is this to be observed in all cases of quenching of alloy or indeed any other steels: Following the quench, the piece quenched is in a condition of great strain and is liable to crack. This liability to crack persists until the piece has been drawn, and it is therefore wise to draw the piece as soon as possible after the quenching.

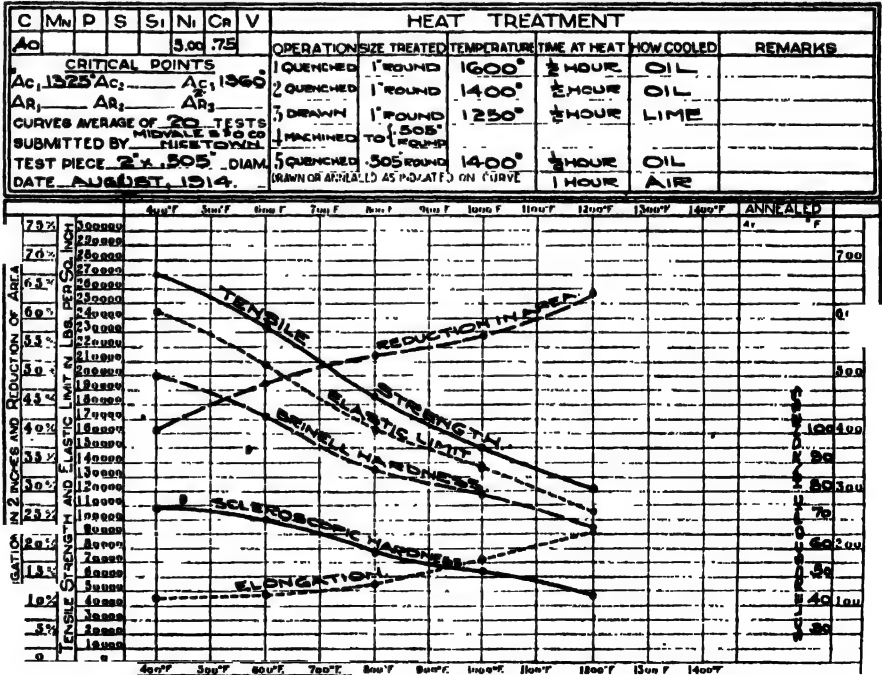

FIG. 11. PHYSICAL PROPERTIES OF A NICKEL : CHROMIUM STEEL RESULTING FROM PROPER PRELIMINARY TREATMENT AND VARYING DRAWING TEMPERATURES

In cases where a drastic quench is advisable it is better to remove the piece from the quenching medium before it becomes entirely cold. By this procedure, the great proportion of the condemnations due to cracking is avoided.

RELATION OF FIBROUS FRACTURE TO SHOCK RESISTANCE

One of the significant effects of a correct heat treatment on alloy steels, which is indeed a criterion as to the efficiency of the treatment, is the production of a peculiar type of fracture in a broken piece, known as "fiber." This fiber fracture is absolutely distinctive, and cannot be mistaken by one who is even slightly skilled in inspection.

It is produced in all of the well melted shock-resisting alloy steels by proper heat treatments, and is so closely related to impact test values that rejected impact tests can almost invariably be selected from passed impact test bars by the absence of this type of fracture. The ease of producing fiber by heat treatment is a criterion of the value of an alloy for shock-resisting properties. So important is the presence of this fracture that armor plate, which must withstand shock test of the most severe character, is never knowingly shipped without possessing it.

Philadelphia, Pa.

The Coal Industry of Swansea, Wales

Swansea is one of the principal coal-producing centers of Great Britain, as well as one of the leading coal-exporting ports. A large part of the consular district is underlain by the coal fields of South Wales. The coal produced is anthracite, semi-anthracite and bituminous. Swansea is, in fact, the chief anthracite center of Great Britain. It is also the center for the manufacture of patent fuel (briquets and ovoids made from coal dust).

The output of the mines of the district before the war was about 9,000,000 tons for all purposes. The output for 1919, however, was only about 6,500,000 tons. Most of the coal produced in the district is exported to other British ports and to foreign countries. The export (coastwise and foreign) trade of Swansea with its sub-port of Port Talbot for 1913, 1918, and 1919 was, in long tons:

Articles	1913 Tons	1918 Tons	1919 Tons
Coal and coke.....	6,743,640	3,845,407	4,434,922
Briquets.....	1,175,119	1,014,603	1,092,803
Total.....	7,918,759	4,860,010	5,527,725

The quantity of coke exported was negligible.

EXPORT QUANTITIES AND PRICES

The Government Coal Control has limited the coal trade of Swansea in two important ways: It has fixed the maximum domestic prices of coal, the present average retail price being about 45s. (\$10.95 at normal exchange) per ton delivered; and it has fixed the minimum supply of coal to be delivered for domestic use, thereby limiting the quantity available for export. Since the output has fallen off considerably during the past twelve months (owing to strikes, shorter work days and decreased output efficiency of workers), this means that the quantity of coal now available for export from this district is far less than it was in former years. The total amount exported from Swansea and Port Talbot for the month of April, 1920, was 220,000 long tons, according to the customs returns for the two ports.

No control is now exercised over the price of export coal, and the prices have risen enormously owing to

shortage of supply and sharp foreign demand. For instance, the average price of best anthracite coal in October, 1919, was 60s. 6d. (\$14.72 at normal exchange) f.o.b. ship, Swansea; for December, 69s. 1d. (\$16.81); in May, 1920, 85s. (\$20.69). Prices of best steam coal at the same dates were 75s. (\$18.25), 88s. 7d. (\$21.56), and 117s. 6d. (\$28.60). The price to-day for run-of-the-mine grade of soft coal is 107s. 6d. (\$26.16). With freight around 50s. (\$17.17) to French Atlantic ports (Rouen or Bordeaux) and 62s. 6d. (\$15.21) to Genoa, Italy, this would make the c. and f. price on run-of-mine coal at French ports 157s. 6d. (\$38.33 at normal exchange, or \$30 at current exchange for sterling), and 170s. (\$41.37 normal exchange, or \$32.38 current exchange) for Italian ports.

CONTINENTAL DEMAND EXCEEDS SUPPLY

Despite these almost prohibitive prices (greatly enhanced by the adverse French and Italian exchange on London), the Continental demands upon the Swansea coal market far exceed the supply of that market. There is ample tonnage at hand, but vessels have to wait an average of sixteen days before securing a berth at the coal piers, so meager is the supply of coal coming to the pier tips.

In view of this condition, and the slight prospect which those interested see of early improvement, many of the local coal-exporting firms are negotiating or have already negotiated contracts with American coal companies for stocks to supply their Continental customers, the coal to be shipped direct from American to Continental ports.

Market for Chemicals in Finland

The total value of the imports of chemicals into Finland during the years 1913 to 1919 is given in the following table, in marks, with the share of each country in this trade during the years 1913 to 1917 (the normal value of the Finnish mark is \$0.193, but the present foreign exchange cable rate is about \$0.05).

From	1913 Marks	1915 Marks	1916 Marks	1917 Marks	1918 Marks	1919 Marks
Russia.....	204,117	3,628,396	14,999,789	12,113,125
Sweden.....	127,113	10,651,673	26,748,867	21,489,487
Germany.....	2,456,262	2,759	652
Great Britain.....	1,853,290	5,050	2,229	5,769
Italy.....	1,576,393	48
Belgium.....	760,113	1,000
Netherlands.....	773,299	21	208	5
Other countries.....	79,350	86,121	294,818	5,228,532
Total.....	7,849,939	14,374,949	43,260,712	38,831,144	5,213,157	22,728,126

These chemicals consist of potash, alum, ammonia (salammoniac) and salts of ammonia, potassium nitrate (pure and commercial), Chilean saltpeter, soda, sodium sulphate, borax, chloride of lime, copper sulphate, heavy-spar sulphuric acid, hydrochloric acid, nitric acid, sulphur, phosphorus, arsenic acid, compounds of arsenic, potassium chromate, potassium chlorate, magnesium, sugar of lead, cream of tartar, tartaric acid, citric acid, calcium carbide. In addition to these chemicals, dyes, drugs and tanning materials are extensively used. Germany has been the principal source of the chemical supply. Extracts and tanning materials are imported from England and sulphur from Italy.

Statistics are not available as to the value of the imports by countries for the years 1918 and 1919. It is noteworthy that 1916 is the first year in which there is recorded an import of chemicals from the United States. During 1919 almost the entire supply of sulphur came from the United States; also considerable quantities of tanning extracts and some drug supplies.

When a Workman Overdoes Himself

BY CHESLA C. SHERLOCK

IT IS not at all uncommon for workmen who are intensely interested in their work, or in a great hurry, to overexert themselves or attempt too much and thereby receive injuries which they ordinarily would not incur under normal conditions. Strains, overexertions, ruptures or hernias are all the logical result of such overexertion. These injuries sometimes are as powerful a contributing cause to the workman's incapacity for work as anything that could be called to mind.

Employers are naturally anxious to know what their legal liability in such cases is, particularly in those employments where workmen are peculiarly liable to suffer such strains or overexertion. Industrial accident statistics place the greatest risk from this nature of injury upon factory helpers—those required to move materials from one place to another, or those engaged in so-called "heavy" work.

Then, again, a strain or an overexertion may be due to the fact that the employer has attempted to make his workmen do a task without sufficient help, one so big that it overwhelmed them. The question arises here, Is the employer liable for his failure to furnish sufficient help to accomplish successfully the object he had in mind?

IS STRAIN AN "ACCIDENTAL" INJURY?

The workmen's compensation acts, as most employers know, provide compensation for accidental injuries received arising out of and in the course of the employment. The principal question which has agitated employers and the courts has been whether a strain can be deemed an "accidental" injury.

In a New York case, the Industrial Commission found "that while claimant was working for his employer at his employer's plant, and was assisting another employee in lifting a barrel weighing about 200 lb., he was seized with a stroke of apoplexy by reason of the strain occasioned by the lifting of the heavy barrel. By reason of the apoplexy, that portion of the brain in which the apoplexy was seated degenerated and while the claimant gradually recovered from the motor paralysis of the left side which immediately followed the apoplexy, there remained a deterioration of his mental faculties due to the above-mentioned degeneration, by reason of which apoplexy and degeneration claimant was disabled from working from the date of the accident to the date hereof and is still disabled." The Commission held that this was a compensable accident.

Where death is caused by reason of the strain or the overexertion, the court in Canada has said: "If an accident necessitates an operation and death ensues, even though it is not a natural or probable consequence, the death may, if the chain of causation is unbroken, be said to have in fact resulted from the injury."

HERNIA A CAUSE OF CONTROVERSY

Hernia has always been the subject of much controversy. This is probably due to the fact that medical men are not entirely agreed among themselves as to what causes hernia. There are two theories—one that it must be the result of an accidental breaking down of the abdominal walls due to strain or overexertion, the other that such a hernia is an impossibility and

that it must always be the result of a disease or a predisposition to hernia.

The Iowa Industrial Commissioner has fittingly stated the general rule of law on the subject when he said: "Hernia may or may not be compensable according to the rules commonly observed in various jurisdictions. Compensable hernia results from specific accident or incident involving unusual condition, such as a strain or a fall or other fortuitous experiences which may be definitely described as to time and circumstance, and attended by demonstrations of distress at the time the injury occurs. In cases where hernia is of gradual development, where alleged injury is unattended by distinct incident and at a date that cannot be definitely fixed, and when the workman is able to continue his service, arbitration cannot be encouraged as giving premise of compensation."

One authority has said: "A hernia, in order to be entitled to any indemnity, must appear suddenly, must be accompanied by pain, and must immediately follow an accident. There must be proof that hernia did not exist prior to the accident."

OPINION OF A MEDICAL AUTHORITY

A well-known medical authority has said: "The proviso that the injury to the inguinal region must have been due to direct violence, or that the accident or overexertion to which the hernia is attributed shall have been of a character capable of producing a hernia, needs no explanation. Since there might be much discussion of what produces accidents capable of producing hernia, the more specific statements given are welcome aids: Direct violence, slipping or falling while throwing a heavy weight, extraordinary exertion, whether extraordinary in an absolute sense or extraordinary from the standpoint of the physique or age of the individual, or the conditions under which the work was being performed.

"An industrial hernia is undoubtedly always small when it first appears, and to estimate its maximum size as that of an egg can hardly work an injustice. To me it seems less safe to say that in traumatic hernia the inguinal ring is always small, barely admitting the tip of the index finger. Brandenburg considered any ring which admitted more than the tip of the index finger, or the absence of a true inguinal canal, a predisposition to hernia. . . .

"A recent hernia is tender, and painful on manipulation, and an ecchymosis is not infrequently present. Immediate strangulation is common, and it is said that the majority of cases judged traumatic and granted compensation in Germany are cases in which the hernia was strangulated when it first appeared."

The employer cannot be charged with the payment of compensation in cases where the workman is uncertain as to the manner in which he received the hernia. If he cannot fix the time and the place and the manner definitely and to a certainty in the evidence, he has not suffered such a hernia as will entitle him to compensation.

If the hernia is the result of an actual accident, a traumatic injury, then it is compensable; if it appears gradually under circumstances bewildering even to the claimant, then it is not a compensable injury in that it is not accidental.

In those states where the payment of compensation is not based upon "accidental" injuries, but upon

"personal injuries," as in Massachusetts, then hernia will be compensated under circumstances not so favorably received in other jurisdictions where the line is more sharply drawn.

In a Wisconsin case it was held that a violent straining of the muscles, resulting in a rupture or other bodily hurt from physical overexertion in performing work is included within the term "accident" used in the compensation act. Thus, muscular spasm caused by straining the muscles of the right side while attempting to lift a heavy cement block is an accident within the meaning of the act.

In Iowa it was held that death resulting from a ruptured artery was not accidental when a factory workman stood on a chair and reached out to close a window during a rainstorm and did not slip or fall or lose his balance and nothing unforeseen occurred except the bursting of the artery.

In a New York case, the employee suffered from the result of a cerebral hemorrhage induced by overexertion. The claimant's physician testified that the injury was "rupture of the cerebral artery on the right side, producing a clot of blood on the brain and suffering the complete paralysis of the left side." The claimant was awarded compensation.

Electric Heat Treatment of Ball-Bearing Races

The Electric Furnace Co., of Alliance, Ohio, recently placed in operation an automatic electric heat-treating set for treating ball- and roller-bearing races at the Standard Roller-Bearing plant of Standard Steel & Bearings, Inc., Philadelphia, Pa.

This equipment is composed essentially of a through type of pusher furnace, an oil-quenching tank and an oil-drawing bath, all arranged in series for a continuous flow of material. Both the furnace and oil-drawing tank are electrically heated.

The flow of material through the heat-treating set is regulated by a clock contactor, which is shown, together with its electrical control, at the left of the furnace in Fig. 1. The intervals between contacts may be varied over a considerable range to accommodate different classes of material.

The hardening furnace (Fig. 1) is of the Electric Furnace Co.'s standard carbon resistor type, and is

FIG. 1. CHARGING END OF HEAT-TREATING SET

FIG. 2. CONVEYOR LIFTING CONTAINER FOR QUENCHING BATH PREPARATORY TO SLIDING INTO DRAWING TANK

rated at 150 kw. It is equipped with pyrometric control and for average tool steel is maintained at 1,525 deg. F.

The drawing tank has nichrome resistors immersed below the oil surface, and arranged along the sides of the tank, the oil being maintained at a temperature of about 350 deg. F. by means of an automatic temperature controller. About 40 kw. is required for the drawing tank when in operation and handling 1,000 to 1,200 lb. of material per hour.

In operation, rings or other small parts to be hardened are placed in perforated metal trays shown in Fig. 2, holding approximately 125 lb. These trays are then placed on a sill in front of the motor-operated pusher. At intervals corresponding to the setting of the clock contactor, the doors open and the tray is pushed into the furnace. At the same time a tray of material which has reached the correct hardening temperature is pushed out of the far end of the furnace and slides down an incline into oil, where it is quenched.

A motor-operated centrifugal pump, started when the door opens, forces a current of oil up through the perforated bottom of the tray almost with sufficient force to float the rings, the object being to chill the rings quickly and to prevent the formation of vapor films or pockets around the heated stock. The length of time the trays remain in the quenching bath is determined by the setting of a small synchronous-motor timing-element by means of which the time can be varied from 1 to 4.5 minutes. At the expiration of this determined time, the tray is removed from the bath by means of a motor-driven inclined sprocket chain shown in Fig. 2, the tray draining of surplus oil until another cycle commences, when a further movement of the chain feeds the tray into the drawing tank. Here, the trays move slowly and continuously forward carried on an independent sprocket chain, which is in turn supported on steel guides. The time required for a tray to pass through the drawing tank can be varied by a gear-set very similar to the speed-changing gears of a lathe.

This arrangement thus gives an exacting control of both time and temperature and is so flexible that it can be quickly changed to fit almost any schedule or conditions required in heat treatment.

New Type of High Vacuum Pump

The Newark Engineering & Tool Co. has recently developed a high vacuum pump. In most all cases, such pumps are immersed in oil to prevent leakage; but in this new design, the engineers have departed from the usual practice of having the pump body immersed in oil. The pump is sealed by means of oil, internally only, thereby saving all the oil used in the outer casing.

Owing to these new mechanical features, from 80 to 90 per cent of the oil can be saved as well as con-

HIGH VACUUM PUMPS FOR AUTOMATIC EXHAUST MACHINES

siderable trouble which is coincident with the use of oil. This pump was especially designed for use in the manufacture of incandescent lamps, and has proved adaptable for X-ray, rectifying, vacuum furnaces and scientific research.

The single pump weighs 50 lb. It has a 7½-in. pulley for round belt. A speed of between 275 and 300 r.p.m. is recommended with a ½-hp. motor.

The accompanying illustration shows three pumps, mounted on a common pedestal, adaptable for automatic exhaust machines used in the lamp industry.

New Solder for Aluminum

The difficulties encountered in attempting to solder aluminum are familiar to all who have experimented with the multitude of so-called aluminum solders which have appeared within the last few years. One of the chief sources of annoyance has been the tendency for electrolytic corrosion to set in at the joint, the aluminum being corroded, since the components of these solders are electro-negative to aluminum. This difficulty has been successfully met and a new solder, the components of which are located so close to aluminum in the electrochemical series that electrolytic action is rendered negligible, has been placed on the market by the Rohde Laboratory Supply Co. of New York City.

This material—which is called "Al-Solder"—is applied at a temperature of about 500 to 600 deg. F., so that warping and other mechanical disturbances are avoided. After a moment's heating, an exothermic reaction takes place with the formation of an alloy. Since an alloy is formed with the aluminum, the durability of the joints is permanent and the seams can be made invisible by polishing, which is very desirable in instrument work, etc. Furthermore, the joint may be reheated without injury so that an additional piece may be joined on without any trouble.

Al-solder may also be used in soldering copper. It is a quick and ready oxide remover and flows in any commercial grade of soft solder under the most difficult conditions. It is hygroscopic and consequently must be kept in an airtight container.

Synopsis of Recent Chemical & Metallurgical Literature

Fatigue Strength of Aluminum.—In order that aluminum may maintain its present growth in output, W. A. GIBSON contends that the user should be convinced of the fact that castings and forgings of its alloys may be introduced into places where strength is most desirable, and weight but a secondary consideration. In his paper, "Fatigue and Impact Fatigue Tests of Aluminum Alloys," read before the 1920 meeting of the Society for Testing Materials, he presents the results of a long series of experiments, which show a sharp distinction between the alloys as cast and those as forged, the properties of the former being very sensitive to melting, molding and pouring practice. Testing in a White-Souther machine (rotating cantilever) and plotting stress against cycles on semi-logarithmic paper, the deviation from a straight line is very marked at low loads, bending upward in such a way that extrapolation would be sure to give largely excess safety. Cast aluminum is liable to vary widely as to yield point and proportional limits, yet the maximum stress, hardness, and the fatigue resistance are relatively close, showing that the ultimate depends upon a different combination of properties than the elastic strength. Only one series of cast iron fatigue tests were available, but it is located close to the curves for cast aluminum. Steady pounds are resisted better by ductile materials—thus the Charpy impact test is comparable to ductility measurements. This is not true for alternating non-impact tests, however.

If comparison is made between duralumin and carbon or nickel steel, weight for weight, the aluminum alloys are found to be equal or superior under impact fatigue, a type of stress ordinarily encountered in machine parts.

Nickeling Aluminum and Aluminum Alloys.—Up to the last few years the nickeling of aluminum and of its alloys has been considered impossible of realization with satisfactory results, especially as to good adherence of the nickel coating. LEON GUILLET and MAXIME GASNIER have studied this problem and have presented the results of their work before the French Academy of Sciences (*Comptes Rendus*, May 25, 1920, pp. 1253-1256). Micrographic examinations of nickeled products showed clearly that the adherence of the coating is a function of the efficient penetration of the nickel in the cavities of the product to be nickeled. Very satisfactory results were obtained on sand-blasted parts. The conditions influencing this operation are:

- (a) Rapidity of the sandblast, which is a function of the pressure of the air used and of the airpipe.
- (b) Size of the grains of sand.
- (c) Time elapsed between sandblasting and nickeling.

- (d) Thickness of the layer of nickel.

The conclusions to which they arrived are:

1. Best results are obtained by using sand passing through a 0.2 mm. (0.008 in.) mesh sieve.
2. The most convenient pressure for the sandblast is 1.5 kg. per sq.cm. (21.5 lb. per sq.in.).
3. The nickeling is not affected appreciably by the

length of time elapsing between the sandblasting and nickeling.

4. The best adherence is obtained when the thickness of the coating is not more than 0.01 mm. (0.0004 in.).

They have also worked on nickeling by using an intermediate layer of copper. The entire operation consists of:

Sandblasting with 0.2 mm. (0.008 in.) size sand under a pressure of 1.5 kg. per sq.cm. (21.5 lb. per sq.in.); nickelplating to a thickness of 0.006 mm. (0.00024 in.) which requires 0.5 hr. with a current of 0.8 amp. per sq.dm.; copperplating to a thickness of 0.02 mm. (0.00079 in.) which requires 2 hr. with a current of 1 amp. per sq.dm.; polishing; nickelplating to a thickness of 0.005 mm. (0.0002 in.) which requires 1 hr. with a current of 1 amp. per sq.dm.; polishing.

This last method of nickeling gives excellent mechanical and chemical results. The electrolytic baths used were:

For nickeling: 150 g. nickel sulphate and 50 g. nickel-ammonium sulphate per liter of water.

For coppering: 150 g. copper sulphate and 20 g. sulphuric acid per liter of water.

Recent Chemical & Metallurgical Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Electrolytic Process.—In the electrolysis of impure copper solutions such as are obtained in leaching copper ores with sulphuric acid there is usually present ferric sulphate, which has deleterious effects on the efficiency of the operation. The presence of ferrous sulphate is not particularly harmful, however. During electrolysis copper is deposited at the cathode and sulphuric acid and ferric sulphate liberated at the anode:

The ferric sulphate will combine with the copper deposited on the cathode and is reduced to the ferrous condition:

The result of these reactions is a loss in current efficiency; if, however the ferric sulphate can be reduced by a comparatively cheap reducing agent, such as hydrogen sulphide or copper sulphide, sulphuric acid is regenerated and the ferric sulphate will not combine with deposited copper, the efficiency of the process being thereby improved.

Apparatus is described whereby the process can be carried out. (1,340,826; WILLIAM E. GREENAWALT, Denver, Col.; May 18, 1920.)

Production of Carbon Monoxide.—In order to reduce to a minimum the amount of carbonaceous material employed in the recovery of metals from their oxides ANTONIUS FOSS and B. J. HALVORSEN, of Christiania, Norway, treat the carbon dioxide obtained from the reduction of metallic oxides or from other sources with metallic sulphides in a suitable furnace. As an example

iron sulphide will react with carbon dioxide as indicated in the equations:

The reaction commences at about 600 deg. C., but proceeds better at higher temperature up to about 1,000 deg. C., if the sulphide treated is not fused. The sulphur dioxide is removed by scrubbing towers and may be used in the manufacture of sulphuric acid, sulphite of lime or liquid sulphur dioxide, and thus carries a substantial part of the cost of the process. (1,340,480; May 18, 1920.)

Production of Iron Without a Blast Furnace.—The modern blast furnace is the accepted apparatus for producing iron from its ores, but requires large-scale production, necessitating a large capital investment. It is also inefficient in consumption of fuel and in the utilization of relatively small sizes of ore, fuel and flux. GUYON F. GREENWOOD, of Georgeville, Que., has developed a metallurgical method and apparatus for the production of iron which avoids many of the disadvantages of the blast furnace. The essential features are the reduction of iron oxide by means of carbon with the exclusion of air in an electric resistance furnace and at a temperature and pressure favoring the production of carbon monoxide, the latter being used as fuel in a gas engine and generating electric energy utilized in heating the electric furnace.

The process is preferably carried out as illustrated diagrammatically in the figure. The furnace 41 pro-

APPARATUS FOR THE PRODUCTION OF IRON WITHOUT A BLAST FURNACE

duces coke from coal which is fed into the furnace from hopper 40 and preheated by the heat in the exhaust gases from the gas engine 44. The fuel for the engine is obtained from combustible gases from the coking of the coal after passing through scrubber 43. Ore and flux, together with the coke, are fed into furnace 52, the ore and flux being preheated in hopper 51 by the heat in the exhaust gases from the gas engine 56. The furnace 52 is maintained at a temperature of about 750 deg. C. and at a slight vacuum without the admission of oxygen. The iron oxides are reduced without producing a slag, and carbon monoxide results which is used as fuel for engine 56. The reduced charge is fed into the electric furnace 59, the impurities slagged off and the iron refined. A minimum amount of heat is wasted and sufficient power is developed by the gas engines to furnish the electric energy for the electric furnaces. (1,338,439; April 27, 1920.)

Coolidge Wrought Tungsten Patent Is Declared Valid

THE Coolidge wrought tungsten patent, under litigation for nearly five years, has been declared valid and infringed in a decision handed down early in July by Hugh M. Morris, Judge of the United States District Court, in the suit brought by the General Electric Co. against the Independent Lamp & Wire Co. of New Jersey.

In the court's opinion the following points in the development of ductile tungsten and the process for producing it were considered:

The history of tungsten for upward of a century after its discovery in 1781 is brief. . . . From the beginning of the nineteenth century efforts were made to cast it, reduce it to plates or draw it into wires, but, with certain possible exceptions which will be hereinafter considered, it was with frequency and uniformity pronounced hard, brittle, unworkable and non-ductile. As late as 1903 Sir Robert Hadfield, a leading metallurgist, in a paper read before the British Iron and Steel Institute, said: "As far as we know the metal tungsten, like chromium, is not malleable. If an absolutely pure metal could be obtained, possibly this statement might have to be modified, but the purest forms which the author has been able to obtain possess hardness, brittleness, and are not ductile either in the ordinary or heated condition." . . . Chemists and metallurgists continued to say that tungsten, whether cold or hot, was neither malleable nor ductile; that it could not be drawn into wires. For instance, in "The Petty Metals, Titanium, Tungsten, Molybdenum," by Truchot, published in 1905-6, it is said: "Like chromium, tungsten is not malleable or ductile, whether cold or hot. When pure, it is hard and brittle." In Roscoe & Schorlemmer's Treatise on Chemistry, revised by Sir H. E. Roscoe, F.R.S., and Dr. A. Harden, in 1907, it was stated: "The purest forms of tungsten at present obtainable are hard and brittle, and are not ductile either at ordinary temperatures or when heated." Even as late as 1910, in "Illumination and Photometry," by Prof. Wickenden of the Massachusetts Institute of Technology, this statement occurs: "The metallurgy of tungsten is very complex and the metal when refined is non-ductile." Consequently a problem remained to be solved. It was said: "The elimination of this excessive brittleness is the crux of the tungsten lamp problem."

COOLIDGE REVOLUTIONIZES USES OF TUNGSTEN

The specific problem was how to make ductile a metal naturally and normally non-ductile. To the solution of this problem the lamp manufacturers in Europe and America bent their every energy. Coolidge solved it and produced wrought tungsten or "Coolidge metal" having properties differing most radically from those of the normal or natural tungsten metal. Tungsten is non-ductile, Coolidge metal is remarkably ductile; tungsten is absolutely brittle at ordinary temperatures, Coolidge metal is pliable and flexible; tungsten is fragile and easily broken, Coolidge metal is stronger than steel. The new metal is so ductile it may be drawn into wires uniform in quality miles in length; it is so flexible that it can be tied in a knot or used as a thread to sew on buttons; its tensile strength may run as high as 600,000 lb. per sq.in., while the tensile strength of steel piano wire, the material next in strength, is only about 400,000 lb. to the sq.in.

The announcement of the Coolidge achievement caused much comment. The United States Geological Survey Report for 1910, "Mineral Resources of the United States," published in 1911, says:

No important new uses for tungsten came to the notice of the Survey during the year, but such wonderful improvements were made in the manufacture of tungsten incandescent electric-lamp filaments as to make their use amount almost to a new one. The General Electric Co. so developed the drawing of tungsten into fine wire that, as now made, it is about as strong as steel wire. This has made possible not only the shipping of tungsten lamps with a very small loss from breakage of the filament, but railroad trains and automobiles now carry tungsten incandescent electric lamps. To railroads this means a very great saving in electric power, with a consequent lessening of the weight of storage batteries used or a lengthening of their period of service per charge; or it means that a smaller dynamo will light the train. . . . The toughening of the filament has also made more practicable lamps of large candle power. Tungsten lamps are now used almost everywhere electric lighting is used.

. . . The ductile tungsten filament has gone into general use and has in large measure if not entirely supplanted all other filaments, including that of Just and Hanaman for incandescent electric lamps. It is less expensive to produce, yet it has far greater durability and utility than the squirted filament. It is a commercially new product of great utility having properties and characteristics unknown to the natural and normal tungsten, or, in fact, to any other material. . .

CHARACTERISTICS AND METHOD OF WORKING TUNGSTEN

We may now examine the characteristics of tungsten and the method of working it. A mass of crystalline tungsten, however fine grained, is entirely brittle cold. It may be worked above its annealing temperature, which is exceedingly high, but after being so worked it is still entirely brittle cold. If the mass is worked at a high temperature, but below its annealing temperature, the grains are deformed. This hardens the metal and makes it less workable at the immediate working temperature, but increases its workability at some lower temperature, an entirely new phenomenon. If worked at the lower temperature, the same results follow. At each stage the grains are drawn more and more until a very fibrous structure is produced which is pliable and ductile cold. If the metal is heated to its annealing temperature at any working stage or after the working has been completed, it reverts to its crystalline condition in which it is entirely brittle cold. The most workable condition of other metals is the least workable condition of tungsten and *vice versa*.

It is thus seen that the characteristics of tungsten are peculiar to it and that the method of working tungsten is an exact reversal of the metal-working processes of the prior art, although heat and mechanical forces are used in each. Never with the exception of tungsten have heat and mechanical forces produced ductility in a metal. Furthermore, tungsten is made ductile by working it under its annealing temperature, a method by which brittleness in other metals is uniformly produced.

THE IMPORTANT THING IN THE PATENT

The important thing in this patent, at least so far as the process claims are concerned, is, therefore, a method of procedure, not the particular means by which the method shall be practiced, yet the specifications point out not only the method of procedure but also complete mechanical devices whereby the method can be put into

operation, though the mechanism is not claimed by the patentee. Working tungsten was the ultimate problem, not the preliminary one. It was first necessary to produce the tungsten in a proper condition, next get it into a mass such as an ingot, billet or slug suitable for working, and lastly to work that ingot into the desired filament or wire.

Each problem presented innumerable difficulties. Coolidge's first discovery consisted in finding that a small filament of tungsten prepared in a particular way could be hammered at high temperatures and its form thereby changed. Upon becoming cool the metal so hammered was still brittle. Experiments disclosed that the brittleness was due not to impurities, but was inherent in the nature of the metal itself. Coolidge attempted to draw a filament through wire-drawing dies. He failed. Subsequently, by heating the filament, the die through which the filament was being drawn and the tongs by which it was being drawn, he succeeded. He succeeded in putting the filament through a second die with a draft a fraction of a thousandth of an inch less than that of the first die. The process was continued with die after die. Eventually he discovered that the remarkable thing had been accomplished, yet the filament so ductilized was little more than a laboratory curiosity owing to the smallness of the original mass. The process, though it produced the new product, produced it only in small quantities and at great cost. It seemed inherently inapplicable to ingots of substantial size. Nevertheless Coolidge through years of effort and failure evolved a process by which masses of tungsten substantial in size could be converted into filaments ductile when cold. The method so evolved is the process that revolutionized the electric lamp industry and is the preferred process of the patent.

DEFENDANT ATTEMPTS TO SHOW ANTICIPATION

The solution of the tungsten problem involved invention. The defendant, however, cites certain publications and patents to show anticipation of the Coolidge invention. Among the most important of these is the publication of Moissan, an eminent French scientist, who, in his work "Le Four Electrique," published in 1897, translated by Lenher, when referring to tungsten, said: "When it is porous, like iron, it has the property of being welded by hammering much below its melting point." Moissan placed in a carbon crucible a mixture of tungsten oxide and carbon and heated it by an electric arc. The outer portion of the resulting mass contained carbon absorbed from the crucible and was very hard and brittle. The inner portion of the mass was the porous tungsten of which Moissan speaks. Coolidge tried the Moissan process. He testified: "We were able to take from the center portions which were very porous which could be, by hot working with a hammer, compacted to a certain extent. Upon attempting to really hot-work these pieces—that is, in the sense of elongating them—they cracked all to pieces. It seemed clear to me from Moissan's publication that all he had done was to produce a porous mass of tungsten which could, by hammering, be compacted to a certain extent, and when we, with excellent facilities, tried to go further and make some use of this material, we were unable to do so."

MOISSAN'S CONTRIBUTION A LABORATORY EXPERIMENT

Moissan's contribution was a laboratory experiment that has never proved of any value in practice. Apparently it taught the world nothing. It is inconceivable

that Just and Hanaman could have attained fame by their inferior fragile squirted tungsten filament if those skilled in the metal-working art had learned from Moissan years before how to work tungsten. Dr. Liebmann testified that he performed the Moissan operation and says: "I obtained a product which tallied exactly with the description given by Moissan." But where Moissan stopped, there Dr. Liebmann stopped. I look in vain among defendant's exhibits for a filament drawn from the porous tungsten of Moissan. I am constrained to conclude, therefore, that the Moissan metal cannot in fact be worked and that Moissan did not in truth discover that tungsten is susceptible of being worked. But this conclusion is not supported by inference alone, for enlarged photographs of the Moissan metal hammered by Dr. Liebmann show very little, if any, deformation but do show very large cracks. Manifestly Moissan did not teach Dr. Liebmann how to work tungsten.

COURT REJECTS ANTICIPATION PLEA

Again, it expressly appears from the record that to be workable the tungsten mass must be coherent, not porous. To convert the porous mass into a coherent mass "welding must take place." Yet "under the most ideal conditions commercially available at the present time" tungsten cannot be welded. It would seem that Moissan's hammering closed only a few pores in the spongy mass. We have seen above what Sir Robert Hadfield in 1903 said of tungsten. Moissan failed to teach him to perform the process or make the product covered by the Coolidge patent. Just and Hanaman and Dr. Coolidge, as well as Sir Robert Hadfield and Dr. Liebmann, were uninstructed by the Moissan publication. In fact I do not find that the disclosure of the Moissan publication was sufficient to enable any one to perform the process or make the product covered by the ductile tungsten patent. It necessarily follows that if the Moissan publication did not instruct how to work tungsten in a practical sense it did not disclose that tungsten could be so worked, or that Moissan discovered that it was susceptible of being so worked. "Novelty," says Walker in his work on patents, Sec. 57, "is not negatived by any prior patent or printed publication, unless the information contained therein is full enough and precise enough to enable any person skilled in the art to which it relates to perform the process or make the thing covered by the patent sought to be anticipated."

Dr. Liebmann was formerly an employee of the General Electric Co., where he also worked in its laboratory "on the problem of developing the ductile tungsten filament." He left the employ of the plaintiff about August, 1910, when Coolidge's work had been substantially completed, and went to Europe, where he was employed until October, 1912, in connection with the manufacture of carbon lamps and squirted filament tungsten lamps. He returned to America in October, 1912, and "started at once to install modern machinery for the manufacture of tungsten lamps in the factory of the Independent Lamp & Wire Co. (the defendant), and also to proceed with the manufacture of ductile drawn wire for these lamps." Hence it appears that Dr. Liebmann learned how to draw tungsten according to the plaintiff's method.

For the foregoing reasons that main product and process claims are in my opinion valid. . . . All the claims of the patent therefore will be held valid and infringed.

Current Events

in the Chemical and Metallurgical Industries

Minerals Separation-Miami Contempt Proceedings Dismissed

On July 13, Judge Morris in the United States District Court, Wilmington, Del., gave an order dismissing the petition of Minerals Separation which sought to punish the Miami Copper Co. for contempt of court and restrain that company from continuing to operate its processes which, according to affidavits of Minerals Separation experts, are not more than a mere colorable change in the plaintiff's process. In making the order, the court said:

The plaintiff now charges by petition that the processes employed by the defendant since it stopped using the three processes heretofore adjudged to be infringements are also infringements and prays that the defendant be adjudged guilty of contempt and/or that a further injunction be issued specifically enjoining and restraining the defendant from using such processes.

The defendant by its answer denies that the new methods infringe the patents sued upon and moves that the rule to show cause be vacated and the petition dismissed upon the ground that, due to the character of the new processes, the present procedure is inappropriate for the determination of the questions raised. The plaintiff contends that it appears from the facts alleged that the new methods are the same in principle as those adjudged to infringe and that the defendant has made only a substitution of equivalents resulting in a mere colorable change in the process, while the defendant contends that those facts disclose that it no longer uses the agitation of the patent. Much testimony touching the processes in question has been introduced by the plaintiff before the master upon the accounting now being had. In fact, it is conceded that little testimony of any other nature has so far been presented.

The present issues do not seem to make necessary a review of the cases upon contempt or those in which the procedure by supplementary injunction has been recognized. Although embarrassed by the fact that I do not possess the full knowledge of the intricate facts of this case that might have been gained had the testimony and argument in the main cause been heard by the court as now constituted, I am, nevertheless, satisfied that the facts set up by the petition are not of the character required to sustain a judgment of contempt. Nor do I find that the practice of enlarging an injunction or granting a supplementary injunction has been adopted in this circuit. But, be that as it may, in view of the nature of the new processes used by the defendant as charged by the petition, the questions raised thereby, and the decision of the Circuit Court of Appeals in this case, 244 Fed., 752; I am of the opinion that the plaintiff must obtain the relief to which it is entitled, if any, touching the new processes, either through the proceedings now being had before the master and the decree to be entered thereon, or by a new bill and not otherwise.

On the same day the court gave the following order relative to making Minerals Separation North American Corporation a party plaintiff in addition to Minerals Separation, Ltd.

I have considered the application of plaintiff for leave to file a supplemental bill, submitted with the motion, setting up the filing of a disclaimer as to claims 9, 10 and 11 of patent No. 835,120, and making Minerals Separation North American Corporation an additional party plaintiff, together with the several objections made by the defendant to the filing of the proposed bill, and am of the opinion that it would be in furtherance

of justice to grant the leave to file but without prejudice to the defendant to renew its objections, in a manner then suitable, to the bill when filed, if it be so advised. An order so providing may be submitted.

Progress in the Federated American Engineering Societies

The Technical Club of Dallas, at its meeting June 2, made application for membership in the American Federated Engineering Societies, being the first local organization to apply. At its recent annual meeting held in Montreal, June 28, the American Institute of Chemical Engineers discussed favorably the question of becoming a member of the F.A.E.S. and referred the matter to the Council for definite action at its meeting on July 25. The opinion was expressed, however, that the Institute should be a member of the new organization, even if an assessment was necessary to meet the financial obligation. The board of directors of the American Institute of Electrical Engineers adopted a resolution at its meeting at White Sulphur Springs, W. Va., June 30, approving membership of the Institute in the F.A.E.S., but deferring action on account of the fact that a new board will be instituted Aug. 1. The board of directors of the American Institute of Mining and Metallurgical Engineers discussed the matter favorably on June 25, and referred it to the finance committee to devise means of meeting the financial requirements. The Civil Engineers are expected to consider the report of their delegates to the Washington Conference at the annual convention of their society at Portland, Ore., Aug. 10 to 12.

Eastman Kodak Co. Purchases Plant at Kingsport, Tenn.

The American Wood Reduction Plant at Kingsport, Tenn., has recently been purchased by the Eastman Kodak Co. This plant, located on a 35-acre site, was built during the war and taken over by the Federal Government for the manufacture of wood alcohol. Original cost of the plant is said to have been \$1,100,000.

As the Eastman Kodak Co. is one of the largest users of wood alcohol and has had to depend on the outside market, it has decided to manufacture its own supply. Engineers and officials of the company are said to be now considering the advisability of enlarging the plant to manufacture other chemicals used in photography. The price paid for this property by the Eastman interest is not stated, but it is understood to be about \$1,000,000.

The immense potential possibilities of the South as a source of power, raw materials and plant sites have only recently begun to be appreciated. As an instance of the effect of establishing a large industry in the South it might be stated that the town of Kingsport, which in 1910 had a total population of 200, now boasts of over 10,000 inhabitants. If more industries could be interested in the possibilities of the South, a great deal could be done to develop its natural resources.

Federal Trade Commission Hearings at San Francisco in Minerals Separation Case

Hearings for the purpose of obtaining further testimony in this case were conducted in San Francisco July 6 to 10, 1920. These were a continuation of the hearings begun in New York on April 7 and were to be continued in Salt Lake City, Utah, July 13 to 17, and in Denver, Col., July 19 to 24. The charges against Minerals Separation and other respondents are the suppression of competition by oppressive license agreements and falsely claiming exclusive rights in excess of actual rights in respect to apparatus and processes used in the separation and concentration of ore. They are also charged with discriminating between different users of their apparatus and processes.

E. H. Nutter, chief engineer, and Messrs. Quigley and Roberts, of the San Francisco engineering office of the Minerals Separation North American Corporation, were interrogated regarding the methods used in obtaining lists of companies which were probable or possible infringers of the M. S. process, together with the uses made of these lists and the attitude and action of the field representatives toward infringers. The testimony brought out the fact that no methods which could be considered as threatening or oppressive were in use by the employees or had been in use during the period covered by the indictment. Instruction had been explicit to field representatives to state their connection with Minerals Separation and the object of the intended visit to the plant of a probable infringer, also that the field men should get permission from the official in charge of the plant to inspect the flotation operations.

Other witnesses expressed their opinion as to the terms of the license and the amount of royalty charged licensees. These were declared to be oppressive and excessive. But counsel for respondent brought out the fact that a profit could not be made from the material treated by any other process known to the witness.

MR. HOOVER'S TESTIMONY

The most interesting testimony was that of Theodore J. Hoover, now head of the department of mining and metallurgy of Stanford University. Mr. Hoover was general manager of the Minerals Separation London company from September, 1906, until the end of 1910, or during the period in which the flotation process of the company was being developed. At the time of leaving the employ of Minerals Separation Mr. Hoover took with him files containing information for his guidance in the capacity of consulting engineer to the company. This office he did not fill, and as a result of ex parte proceedings all documents and papers taken by Mr. Hoover were examined by officials of Minerals Separation Company and an agreement reached upon those to be returned.

According to Mr. Hoover's testimony he entered the employ of Minerals Separation under a contract which stipulated that during or after his employment he could not impart to any third party any information regarding the flotation process. These terms were considered at the time to be oppressive in that they restricted his possible future activities. This clause in the contract was also the subject of discussions between Mr. Hoover and Mr. Ballot, president of Minerals Separation, during the term of Mr. Hoover's employment with the company. These terms were never receded from by contract but are evidenced in certain letters to Mr. Ballot written by Mr. Hoover in which he expressed what he considered,

to be fair terms. The Minerals Separation Company has not modified or released Mr. Hoover from the terms of the contract since he left its employ.

Among the exhibits requested in evidence from Mr. Hoover was a manuscript written by H. S. Sulman and H. K. Picard, consulting engineers and two of the inventors of the Minerals Separation flotation process, on the theory of flotation. This manuscript was among the papers which were inspected by the Minerals Separation officials, but was not discussed in particular at the time of the legal proceedings nor was its return mentioned subsequent thereto.

CONSIDERS COMPANY'S CLAIMS EXCESSIVE AND FRAUDULENT

In August, 1919, Mr. Hoover entered the employ of the Miami Copper Co. as consulting engineer. As a result of the knowledge gained through investigation of the evidence afforded in the Miami case, Mr. Hoover became convinced that the claims made by Minerals Separation for its process were so far in excess of the claims made by certain of the inventors of the process as set forth in their treatise as to "constitute an attempt to perpetrate a fraud upon the court." Mr. Hoover resigned his position with the Miami Copper Co., and after consulting legal opinion and obtaining advice from brother engineers, Mr. Hoover considered it to be his public duty to offer the manuscript in evidence. This manuscript was the same one that was submitted in evidence in the flotation litigation between Minerals Separation and the Miami Copper Co., upon which we commented editorially in our June 30 issue.

T. A. Rickard, editor of the *Mining and Scientific Press*, testified that the effect upon the mining industry which resulted from the company's policy of preventing the publication of information regarding the flotation process was to retard development both of the industry as a whole and the process in particular.

Shortage of Anhydrous Ammonia

A serious shortage of anhydrous ammonia, which may occasion great losses of foodstuffs which must be placed in cold storage during the summer, is reported by the Bureau of Markets of the Department of Agriculture. There is no shortage of raw materials. The scarcity of the finished product is attributed to a number of reasons.

During the war large quantities of ammonia were sent to France in drums. The priorities which have existed on ocean freights have precluded the return of these drums. For a long time manufacturers withheld orders for new drums, expecting from week to week that arrangements would be made for the return of the drums in France. Finally when nothing definite could be learned as to when the drums could be returned, orders were placed for new drums. This was about the time of the steel strike and a long delay resulted before delivery could be made. The drums had no more than begun to arrive when the coal strike cut down the output of byproducts from the coke ovens. The next difficulty to arise was the switchmen's strike which has retarded deliveries so as to round out an unusual combination of difficulties which accounts for the fact that there are no reserve stocks of ammonia.

The Bureau of Markets is taking steps to acquaint all users of ammonia with the situation and will urge them to do all possible to prevent waste and to make efficient use of the supplies which they have on hand.

Convention of the American Electroplaters' Society

The large attendance at the convention of the American Electroplaters' Society, held in Rochester, N. Y., July 1 to 3, 1920, and the willingness of the platers and chemists present to discuss their problems and to impart information, augur well for the future of the American Electroplaters' Society, of which this is only the eighth annual convention. The noticeable dearth of technical papers may be accounted for in part by the unsettled business and labor conditions which have no doubt prevented many platers from trying out new or improved methods or of perfecting them to the point for publication. In future conventions such papers probably will be more numerous; in fact they must be, if the society is to progress. To this end the manufacturer should encourage and assist his plater to develop and apply new methods and thus avoid stagnation. In those plants where both chemists and platers are employed, they should work together in a spirit of co-operation, to improve processes and to secure more exact knowledge of existing methods. If for example in each of twenty-five such plants, definite data upon some phase of plating were secured each year, there would be no dearth of papers for future conventions, and a mass of reliable information would soon be accumulated.

USE OF HYDROFLUORIC ACID IN NICKEL-PLATING SOLUTIONS

The subject which received most consideration in the technical sessions was the use of hydrofluoric acid in nickel-plating solutions. This substance has been used so successfully by E. G. Lovering of Detroit that he has christened it the "magic fluid." A preliminary report from the Bureau of Standards described the results of experiments upon the application of hydrofluoric acid in nickel baths used for the electrolytic production of printing plates in the new plant of the Bureau of Engraving and Printing.

This paper was discussed at length by Messrs. Lovering, Allen, Woodmansee, Herrick, Madsen, Hogaboom, Slattery and others. From the paper and its discussion it seems to be clearly established that nickel can be deposited from solutions containing hydrofluoric acid (or ultimately nickel fluoride or fluoroborate) more rapidly than from the ordinary solutions. These deposits are brighter and have a finer structure and higher tensile strength, and are harder but less ductile than deposits produced in the customary baths. The fluoride deposits are therefore more difficult to buff, but for the same reason they show greater resistance to abrasion. Such deposits are likely to be especially valuable in electroplating, or for the nickel plating of objects subject to abrasion in service. The whole subject is greatly in need of more exhaustive investigation, and the chief value of this discussion was to emphasize the great possibilities involved in the study of even such well-known baths as are used in nickel plating.

OTHER PAPERS—PLANTS VISITED

Other papers discussed in the meetings were:

"Anode Hooks," by H. F. Sperry.

"Nickel Plating on Zinc and Die Castings."

"Sanitation in Plating Rooms," by G. Wilson.

"Ball Burnishings," by R. Hazucha.

"Oxidizing (i.e., coloring) Aluminum," by F. J. Hanlon.

Among the plating plants visited were those of the

Eastman Kodak Co., the Taylor Instrument Co., the Bausch & Lomb Optical Co., the Northeast Electric Co., the Van Bergh Silver Plating Co. and the General Railway Signal Co. These manufacturers are to be congratulated upon their broad-mindedness in permitting such inspection, thus advancing the educational aims of the Electroplaters' Society.

BROADENING OF MEMBERSHIP DISCUSSED

The most important business before the convention was the question of admitting assistant foreman platers to associate membership in the society. At present active membership is restricted to actual foreman platers; associate membership is restricted to persons who were formerly foreman platers but are now salesmen for plating supply houses, and to chemists or metallurgists interested in electroplating. After lengthy discussion, the amendment to admit assistant foremen as associate members was referred to a referendum vote of the society. The decision upon this question will be of great importance, not alone to the electroplaters, but also to the chemists and manufacturers, since the future progress of the whole electroplating industry depends upon an intelligent and sympathetic education of those younger men, who will in time become the actual foremen and superintendents.

CO-OPERATION IN STANDARDIZATION AGREED UPON

The society accepted an invitation from the Metal Finishers Equipment Association to co-operate with it in the standardization of materials and supplies used in electroplating. Clear definitions of terms and materials in some cases (with tentative specifications of purity or quality) will be valuable alike to the electroplaters and their employers, and will enable purchasing agents to secure on the open market supplies of adequate and uniform quality, and will permit chemists connected with plating plants to conduct more intelligent control work than when supplies are purchased with no definitions or specifications. The committee on research and standardization, to which this matter was referred, can render great service through such co-operation.

AID FOR RESEARCH WORK

To the same committee was referred the matter of securing, for manufacturers interested in plating, financial support for research work, to augment the limited funds now available for such work at the Bureau of Standards. In this discussion it was emphasized that such support should be viewed by each manufacturer, not as a contribution, but as an investment, certain to yield results of value to him as well as to the whole plating industry.

SOCIAL FEATURES

The entertainment and social features of the convention were very successful and enjoyable. In thus supplementing the business and technical sessions by social gatherings, the delegates and guests not only were entertained, but were also afforded that opportunity for acquaintance and for intimate discussion of their daily problems which is after all one of the chief advantages of a convention, especially for a society which is still almost in its infancy, but showing a healthy growth. Ten years ago such a gathering would have been unheard of in the plating industry. With the spirit shown at this meeting, there is no question of the still greater growth and development in the next decade.

Fertilizer Manufacturers Seek Government Aid to Relieve Car Shortage

Strong representations have been made to the Interstate Commerce Commission and to the committee on car service of the American Railway Association in an effort to secure more cars for the fertilizer industry. Between now and the middle of September, 40,000 carloads of mixed fertilizer should be distributed. In addition 25,000 carloads of fertilizer raw materials must be moved in the near future. It was pointed out that fertilizers were given the benefit of priorities during the war, and that the need for their use is greater now than then.

As a result of persistent efforts farmers have been induced to place their fertilizer orders early this year. This was done with the idea of lowering the peaks in the distribution of fertilizer. The plan worked out more successfully than had been anticipated, but the distribution cannot be carried on in the required volume, as cars cannot be obtained in sufficient number to take care of the transportation.

Due to inability to secure phosphate rock many acid plants have been forced to close, the committee on car service was told. Practically every plant in the country is receiving its supplies in a hand-to-mouth manner. Not less than 250 cars daily are required to handle the necessary phosphate rock from Florida. About 50 per cent of the cars needed are being furnished at present. The same is true of the car supply on the Louisville & Nashville, over which most of the Tennessee phosphate rock reaches fertilizer plants.

The committee which came to Washington to take up the matter of car supply was composed of Spencer L. Carter, Virginia-Carolina Chemical Co.; DeWitt Brown, Armour Fertilizer Works; Robert B. Allen, Smith Agricultural Chemical Co.; T. A. Bosley, Virginia-Carolina Chemical Co.; A. S. Key, Federal Chemical Co.; H. Braunlich, American Agricultural Chemical Co.; J. W. Hoyt, International Agricultural Corp.; D. A. Dashiell, F. S. Royster Guano Co.; Douglass Ober, G. Ober & Sons; A. D. Whitmore, American Cyanamid Co.; Frank G. Moore, Davison Chemical Co.; J. W. White, International Agricultural Corp.

The committee was accompanied by representatives of the Bureau of Soils.

Industrial Research Laboratories in America

A bulletin just issued by the National Research Council lists more than 300 laboratories maintained by industrial concerns in America, in which fundamental scientific research is carried on. The bulletin gives a brief account of the personnel, special equipment and particular kind of research carried on in each of the laboratories listed.

Industrial research laboratories have increased notably in number and activity, both in America and Great Britain, since the beginning of the war, because of the lesson vividly taught by the war emergency. It was only by a swift development of scientific processes that the Allies and America were able to put themselves in a position first to withstand and then to win a victory over Germany's science-backed armies and submarines. And it is only by a similar and further development that America and the Allies can win over Germany in the economic war-after-the-war, now being silently but vigorously waged.

Cellulose Section, A. C. S., Considered

Under the able guidance of Jasper E. Crane, a Cellulose Symposium was organized as a part of the program of the Division of the American Chemical Society last April. One of the objects of this symposium was to ascertain whether a Cellulose Section, if formed, would secure the interest and support of a sufficiently large number of chemists. The object of such a section would be to promote intercourse and co-operation among the chemists in the various cellulose industries. This group constitutes one of the largest and most important of American industries; all branches of it are intimately concerned in the problems of cellulose, and it seems highly desirable to promote technical activity in this country along these lines. The proposed section would serve as a clearing house for papers and information on cellulose technology, and should also play an important part in promoting research on the chemistry of cellulose.

The symposium at St. Louis was distinctly successful. The interest shown was so great that it was voted to hold a second Cellulose Symposium under the auspices of the Industrial Section at the Chicago meeting during the week of Sept. 6. At this time the advisability of forming a permanent Cellulose Section will be considered. An interesting program is being arranged, and a large attendance of those interested in cellulose is anticipated.

Titles of papers or suggestions for the symposium should be sent to G. J. Esselen, Jr., 30 Charles River Road, Cambridge, 39, Mass.

Foundrymen's Exhibit Grows

The growing appreciation of the important work that the American Foundrymen's Association is doing manifests itself in the increased demand for exhibition space at the Convention and Exhibit to be held at Columbus, Ohio, Oct. 4 to 8. Already 51,000 sq.ft. of exhibition space has been contracted for, with 85 per cent of last year's exhibitors to be heard from.

A number of new exhibitors will be on hand this year, especially in the general shop equipment and machine tool lines, as there is a growing appreciation of the extraordinary purchasing power represented in the A. F. A. attendance, aside from strictly foundry requirements. This is due to the fact that many of the men interested in the foundry meetings also operate machine shops.

A striking feature of these annual shows is the large percentage of operating exhibits demonstrating the equipment by duplicating actual working conditions. Last year more than 50 per cent of the 208 exhibitors used power, 170 motors being in operation and 31 exhibitors using compressed air for demonstrating purposes.

Golden Mine Experiment Station Moves to Reno, Nev.

The Secretary of the Interior has approved the transfer of the Golden Mine Experiment Station to Reno, Nev. The station in the future will be known as the Rare and Precious Metal Station and will be conducted in co-operation with the University of Nevada, which will construct a building especially designed for the use of the station. The building is to cost at least \$30,000. Dr. S. C. Lind will continue in charge of the station at its new location.

Personal

F. T. AGTHE has resigned as plant engineer of the Missouri mills of the Atlas Portland Cement Co., Hannibal, Mo., to join the staff of the Hardinge Co., at York, Pa.

Dr. SCOTT E. W. BEDFORD of the University of Chicago spoke before the Chicago Chemists' Club recently on the organization of the Army educational system.

Dr. W. D. COLLINS, formerly in charge of the analytical reagents laboratory of the Bureau of Chemistry, is now in charge of the U. S. Geological Survey, Quality of Water Division, succeeding R. B. Dole. Dr. Collins will continue as chairman of the American Chemical Society committee on standardized reagents and apparatus.

Dr. F. G. COTTRELL, director of the Bureau of Mines, has been designated to succeed Van H. Manning as a member of the interdepartmental defense board of the Council of National Defense.

Dr. P. M. GIESY, formerly of the dyestuff research department, Grasselli Chemical Co., is now in charge of the beta-phthol control laboratory of the Calco Chemical Co., Bound Brook, N. J.

ELMER ALLEN HOLBROOK has assumed the position of assistant director of the Bureau of Mines, succeeding Dr. Cottrell, who is now director of the bureau. Mr. Holbrook entered the bureau in 1917 as supervising mining engineer at the Urbana station, during the first half of 1919 was made acting chief engineer and in July, 1919, was made superintendent of the Pittsburgh Experiment Station, where he was until called to Washington, July 1, 1920.

Dr. LYNN HAROLD HOUGH has resigned from the presidency of Northwestern University, Evanston, Ill., on account of ill health.

M. O. LEIGHTON and Major C. T. CHENERY, members of the American Society of Civil Engineers, and A. C. OLIPHANT, associate member of the American Society of Mechanical Engineers and the American Institute of Electric Engineers, have formed a copartnership under the name of M. O. Leighton & Co., with offices at 700 Tenth St., Washington, D. C., for the purpose of engaging in general engineering practice and industrial representation before the Federal departments. Mr. Leighton and Major Chenery will continue for the time being as chairman and secretary of the National Public Works Department Association, while Mr. Leighton and Mr. Oliphant will continue service in the Washington office of Engineering Council pending the displacement of that body by the Federated American Engineering Societies.

H. C. MILLER, formerly superintendent of the Round Valley Tungsten Co. of California, is now petroleum production engineer with the Standard Oil Co. at Taft, Cal.

CLIVE SEYMOUR NEWCOMB, metallurgical engineer, has resigned his position with the Dorr Co. to become consulting engineer with the Mutual Chemical Co. of America and the Phosphate Mining Co. His address is 55 John St., New York City.

G. ARNCLIFFE PERCIVAL, chief chemist, The Edison Swan Electric Co., Ltd., Ponders End, Middlesex, England, has returned to England after spending several weeks visiting chemical industries of the Eastern United States.

J. LEONARD REPLOGLE, president of the Replogle Steel Co., sailed for England on July 1.

GUY C. RIDDELL, consulting metallurgist, formerly in charge of metallurgical and mining problems for the U. S. Tariff Commission, is now secretary and consulting engineer of the Wah Chang Trading Corp., 233 Broadway, New York City.

G. C. SPENCER has succeeded W. D. Collins, in charge of the analytical reagents laboratory of the Bureau of Chemistry, Washington, D. C.

Bureau of Mines Strengthens Its Chemistry Department

The chemical side of the investigations being conducted at a number of the Bureau of Mines experiment stations is to be greatly strengthened. The personnel at the stations has been arranged so as to make this possible, with O. C. Ralston at Seattle, L. H. Duschak at Berkeley, C. M. Bouton at Salt Lake City, Dr. Thomas B. Hine at Tucson and Dr. S. C. Lind at Reno.

Current Market Reports

The Iron and Steel Market

Pittsburgh, July 16, 1920.

Shipping conditions at the blast furnaces and steel mills have been still poorer in the past week, due to car shortage, the increase in which is generally attributed to the operation of order No. 7 of the Interstate Commerce Commission according to priority to the coal mines. A large steel interest reports its shipment during the first twelve days of this month less than in the same period of June by an amount equal to about 20 per cent of its productive capacity, but such an experience is probably unusual. A rough guess would be that shipments are at about two-thirds of production, assuming that all the steel made is carried through to finished form according to customers' specifications, the fact being that the amount of steel held in unfinished or semi-finished form is increasing.

The iron and steel interests have objected to order No. 7, not so much to the essence of the order as to the terms by which it has been interpreted, as the average railroad has interpreted the term "coal car" in the present circumstances to include all flat-bottom gondolas measuring more than 30 in. high inside. Partly no doubt on account of the representations of the iron and steel industry, the Interstate Commerce Commission, while extending the order for another thirty days, from July 21, modifies the terms whereby coal cars shall include only those gondolas that are 36 in. or more inside measurement. The industry is of opinion that the difference means a very considerable number of cars, and a corresponding increase in car supplies is to be expected.

Among the representations before the commission there was a statement that in four districts, not including the East or the Chicago district, there was an accumulation of steel awaiting shipment amounting to 1,416,727 tons. Including the districts not taken into the reckoning, and allowing also for steel accumulated, for convenience, in unfinished or semi-finished form, the total of the steel accumulations seems likely to be in the neighborhood of 2,500,000 tons. In this report of a fortnight ago estimates were mentioned ranging from 2,000,000 to 3,000,000 tons.

FINISHING DEPARTMENTS CLOSED

The tendency is stronger to close finishing departments and accumulate steel in ingot or semi-finished form. There is little if any voluntary curtailment of steel ingot or of pig-iron production. At one large plant approximately half the finishing mills are closed at a time, but work is alternated, week about, so as to give all the men some employment. At another large plant there is the exceptional case of practically all finishing departments being closed since the first of the month, to resume next week, while the production of pig iron and steel has continued.

In the case of finished steel there is the double difficulty that storage facilities are already taxed, and that steel made to customers' specifications may prove quite unacceptable at the late date at which the steel will be shipped. When that time will be no one ventures to predict, since shipments are still below production and the beginning has not yet been made in clearing off the accumulations.

The Steel Corporation's increase of 38,351 tons in unfilled obligations in June is small compared with the average

of 550,000 tons a month increase of twelve months preceding, but on the other hand it is remarkable that there should have been any increase when the steel market was so dull. The independents as a whole did not boom nearly as much as they produced, nor even as much as they shipped. Month by month the disparity in order books between the Steel Corporation and the independents has increased, on account of the divergence in prices quoted. In actual orders the independents probably do not have on books a tonnage equal to more than two or three months additional of production, though they have made various arrangements with customers to supply them for later periods on the basis of "price ruling at date of shipment." The Steel Corporation, on the other hand, had 10,978,817 tons of unfilled obligations July 1, this of course including something like three-quarters of a million tons of steel produced but not shipped and therefore not invoiced. The corporation's output at 90 per cent of capacity up to April 1, 1921, would be about this same tonnage.

STEEL PRICES PRACTICALLY STATIONARY

The stocks of steel made to customers' specifications but not shipped are perhaps the best preventive possible of price cutting. At any rate, the large independents show no disposition to reduce prices. On bars, shapes and plates their prices are, respectively, 3c., 3.10c. and 3.25@3.50c., as they have been for months past. There has been the still higher market, made by smaller mills for prompt shipment, and this market continues to trend downward. In plates there is approximately a parity between prompt shipment and any shipment the independents can make. The Steel Corporation's prices for the three products remain at 2.35c., 2.45c. and 2.65c., respectively.

PIG IRON ADVANCING

With pig iron accumulating at the furnaces on account of lack of shipping facilities, with deliveries very scant and prices for early deliveries advancing, the pig-iron market appears to be riding for a fall, but it is a market that has furnished surprises before. Both bessemer and basic have sold in the past week at \$46, valley basis, an advance of \$1 a ton over the previously quoted market. Foundry iron remains nominally at \$45, valley, but may easily show an advance if any prompt demand of consequence develops.

While pig iron is high relative to steel and shows a greater spread over its pre-war average than do commodities in general, the price must be considered low when Connellsville furnace coke is bringing \$18 per net ton at ovens for spot or prompt shipment. Why furnaces are willing to pay such a price, even on the very limited tonnages they buy, is not explained, and every week it is reported that the furnaces will no longer patronize the market.

Shipments of Lake Superior iron ore down the lakes in June amounted to 9,233,566 tons, a fair showing for the month, but on account of the backset in April and May the season total to July 1 is only 16,440,505 tons, against 16,008,419 tons in the same period in 1919, whereas a large increase is desired on account of the heavier operation of blast furnaces this year. There is, however, no danger of an actual shortage of ore, and once more the expressed fear of a shortage is seen to be groundless.

The Chemical and Allied Industrial Markets

New York, July 16, 1920.

The break and sudden decline in prices, frequently predicted to occur in other markets, has hit the crude rubber trade and stopped all business. A member of the trade recently returned from Akron on a tour of inspection in company with a man representing English interests reports that matters are in the worst possible condition and that after having seen numerous tire manufacturers he is convinced that there will be no activity until late fall and possibly not until next year.

The present situation is directly traceable to several causes, viz., the enormous quantities of war surplus material in the Indian market brought about a reversal of form, to the extent that the spot market was quoted below future

delivery. This being an unhealthy condition, buying interests realized that a drop was bound to come and held off waiting for a decline. Tire manufacturers by the vast expansion and additions to their plants had given promise of increasing their output about 10,000 tires a day each, which would necessitate a considerably larger amount of rubber. These plans, however, were abandoned when automobile manufacturers cancelled their rubber contracts because of inability to deliver automobiles by freight.

These conditions are verified by a report of the failure of one of the largest and oldest firms engaged in the crude rubber trade. This concern has on its books *Para*, upriver, bought at 55c., and some idea of the amount of money involved can be gained by comparing that price with current quotation of 35c., which it is not beyond reason would be shaded to 32c. on a large order.

GENERAL CHEMICALS

There has been no change in the position of the chemical market during the current week, buying interests still holding off for lower prices. Despite the lax demand, supplies have not appreciably increased and although there have been some drops, noticeably on *acetic acid*, glacial, which is being generally quoted at \$14.50@15.50 per cwt., a quotation on a 5-ton lot as low as \$13.50 per cwt. has been heard. The market has preserved a tone of firmness in the main. Some other items that have changed during the period are *tannic*, tech., now listed at 60@70c. per lb. on car lots, and *ammonium carbonate*, powder, which has come up from 17½c. to 18c. per lb. The demand for *copperas* that has been so strenuous lately seems to have fallen off slightly and as a result stocks are somewhat improved, but sales ranging as high as \$3.50 per cwt. are still being placed. Both *sodium* and *potassium chlorate* have been advanced by producers and the new levels are 11@12c. per lb. for the former and 15@17c. for the latter, while *sodium bichromate* changed in the other direction, with the low mark at 24c., against 26½c. of the previous week. The pressure of increased demand has forced *calcium chloride*, fused lump, up slightly, and it is now difficult to obtain this material at less than \$25 per ton, while the average price seems to be about \$30; in sympathy with this the *granulated* grade also rose, with 3@3½c. per lb. the prevailing quotation at present. Spot supplies of *aluminum sulphate* are giving way under the heavy buying pressure, with 5½c. per lb. for commercial and 6½c. for iron-free grade being asked for material in second hands. Producers are behind in their contracts and are consequently unable to take any new business.

COAL-TAR PRODUCTS

The recent 5c. flat rise on crude bases put into effect by producers seems to have had the effect of strengthening the market. The improvement in the money situation has also helped in this matter, and although there has been no general increase, nevertheless the downward tendency noticed on several items for the past two weeks has stopped. *Naphtha*, flake, is still unobtainable at a reasonable figure, but for those who must have this material it can be obtained on the spot market at 20c. per lb. One large producer is still delivering on contracts written at 9c., and upon arrival it immediately goes into second hands, probably changing three or four times before reaching ultimate consumer. *Alpha naphthylamine* is somewhat easier and it is possible to locate material at 53c. and lower, while *aniline oil* and *salts* are firmer, although there has been no change in price.

NAVAL STORES

The present volume of business, which vastly improved over the last month, would be still greater if the matter of delivery from the South could be adjusted. The low scale of prices on *rosins* prevailing at present is due to the arrival in the primary market of the new crop, which for the present has relieved the pressure in this market. As can be seen from the table, there is slight increase over last week's prices and the listed prices are those which are expected to be in effect for some time. *Turpentine* came up slightly during the week and is now quoted at \$1.58 per gal., against \$1.49 of the previous period.

The Baltimore Market

Baltimore, July 14, 1920.

There is still considerable doubt in the minds of fertilizer manufacturers as to whether they will be able to secure sufficient labor and cars to fill their orders, and the situation during the next few months will be a question of production rather than of selling. This applies particularly to acid phosphate, and the dry mixers who have not yet covered for their wants will doubtless experience difficulty in inducing producers to take on further commitments for car shipments.

Acid Phosphate. The market remains very strong, and the various producers are still more closely sold up than they have been for some time past. It is next to impossible to place orders for car shipments for any important tonnage, and on account of the labor situation none of the producers is disposed to take on business for shipment in buyers' bags either for July, August or September, as it is doubtful whether they will be able to secure either sufficient cars or labor to fill orders from their regular customers. The nominal quotation for 16 per cent grade in bulk remains at \$20 per ton f.o.b. cars, with run of pile testing 17 to 18 per cent being quoted for water shipment at \$19 per ton, basis 16 per cent A.P.A. However, there is very little buying interest manifested by such buyers as are in position to take delivery by water. The market seems stationary at present level, and producers are more concerned in securing crude materials and filling orders now on their books than in market fluctuations.

Tankage. While the Chicago market remains firm at prevailing levels of \$7.75 and 10c. f.o.b. Chicago, with apparently no anxious sellers, there has been a slight easing up in the nearby Eastern markets, where producers are not in position to carry large stocks, and some sales have been made during the past week as low as \$8 per unit of ammonia and 10c. per unit of B.P.L., basis c.a.f. Baltimore, which is considered somewhat below the general market, and any important inquiries would doubtless have the effect of driving prices up to \$8.15@8.25 and 10c. Baltimore.

Nitrate of Soda. While little buying interest is being manifested, the market remains firm, with prices for summer and fall deliveries ranging from \$3.85 to \$4, depending upon tonnage and deliveries, and January-April shipments nominally quoted at \$4.10@4.15. In view of the fact that the production of sulphate of ammonia, on account of the coal situation, is not up to expectations, some of the manufacturers are inclined to show interest in nitrate.

Potash. Up to the present time the new schedule on the Alsatian product for delivery over the balance of this year has not been announced, and in the absence of this manufacturers are showing little interest in the German product, on which prices were fixed some weeks ago. There is considerable speculation as to whether there will be any difference between the Alsatian and German products, although it is generally conceded that higher prices will rule than prevailed last season. There is very little demand for spot potash, and muriate is being firmly held at \$2.65 per unit, with very small stocks of either kainit or manure salt. There is a vessel due late this month from which muriate is obtainable at \$2.50@2.60, kainit at \$2.25@2.35, and manure salt at \$2.15@2.25. For August-September arrival these prices could be shaded about 5 per cent.

Fish Scrap. The prevailing prices on this article have proved so attractive and so much higher than the fish factories have realized for their product for some years past that quite a number of contracts have been booked, subject to catch and "if made," thus assuring producers of at least \$7.50 and 10c. for the dry scrap, f.o.b. their factories. Fish scrap on this basis figures lower than other animal ammoniates.

Bone Meal. The market is practically bare of both raw and steamed bone meal, but such small stocks of 3 and 50 per cent as are obtainable are being held as high as \$54 per ton, in buyers' bags, f.o.b. Baltimore, and even at this price there is only a limited tonnage offered. While the demand for 4½ and 45 per cent raw bone meal is light, resale lots are offering at \$63 per ton, packed in second hand bags, f.o.b. Baltimore, but on account of price being so high buyers are going very cautiously in their purchases.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

	Carlots	Less Carlots
Acetic anhydride..... lb.		\$0.45 - \$0.75
Acetone..... lb.	\$9.15 - \$10.20	21 - 22

Iodine, resublimed..... lb.	4.30 - 4.35	4.40 - 4.45
Iron oxide, red..... lb.		03 - 20
Iron sulphate (copperas)..... cwt.		2.75 - 3.50
Lead acetate, normal..... lb.		13 - 16
Lead arsenate (paste)..... lb.	11 - 12	13 - 17
Lead nitrate, crystals..... lb.		90 - 1.00
Litharge..... lb.	14 - 15	15 - 16
Lithium carbonate..... lb.		1.50 - 1.55
Magnesium carbonate, technical..... lb.	12 - 14	15 - 16
Magnesium sulphate, U. S. P..... 100 lb.	3.00 - 3.55	4.00 - 4.50
Magnesium sulphate, commercial..... 100 lb.		3.25 - 3.60
Nickel salt, double..... lb.		14 - 16
Nickel salt, single..... lb.		13 - 14
Phosgene (see carbonyl chloride)..... lb.		
Phosphorus, red..... lb.	50 - 55	60 - 65
Phosphorus, yellow..... lb.		35 - 37
Potassium bichromate..... lb.	40 - 45	46 - 47

	Carlots	Less Carlots
Potassium bitartrate (cream of Tartar).....lb.	\$0.52 - \$0.56	\$0.57 - \$0.58
Potassium bromide, granular.....lb.	.80 - .85	.90 - .95
Potassium carbonate, U. S. P.....lb.	.47 - .50	.47 - .50
Potassium carbonate, crude.....lb.	.20 - .25	.26 - .28
Potassium chlorate, crystals.....lb.	.15 - .17	.18 - .20
Potassium hydroxide (caustic potash).....lb.	.30 - .33	.35 - .38
Potassium iodide.....lb.	3.35 - 3.60	3.35 - 3.60
Potassium nitrate.....lb.	.15 - .17	.19 - .21
Potassium permanganate.....lb.	.75 - .80	.85 - .95
Potassium prussiate, red.....lb.	.90 - 1.00	1.05 - 1.20
Potassium prussiate, yellow.....lb.	.32 - .36	.35 - .40
Potassium sulphate (powdered).....ton	\$225.00 - 240.00	
Rochelle salts (see sodium potas. tartrate).....		
Sal ammoniac (see ammonium chloride).....		
Salt soda (see sodium carbonate).....		
Salt cake.....ton		40.00 - 50.00
Silver cyanide (nominal).....oz.		1.25 - 1.35
Silver nitrate (nominal).....oz.		.74 - .76
Soda ash, light.....100 lb.		3.50 - 3.60
Soda ash, dense.....100 lb.		3.55 - 3.65
Sodium acetate.....lb.	.08 - .09	.09 - .12
Sodium bicarbonate.....100 lb.	2.45 - 2.60	2.75 - 3.50
Sodium bichromate.....lb.	.24 - .27	.28 - .29
Sodium bisulphate (nitro cake).....ton	7.00 - 7.50	8.00 - 10.00
Sodium bisulphite Powdered.....lb.	.06 - .06	.07 - .10
Sodium borate (borax).....lb.	.09 - .10	.11 - .12
Sodium carbonate (sal soda).....100 lb.	1.50 - 1.80	1.80 - 2.00
Sodium chlorate.....lb.	.11 - .12	.12 - .13
Sodium cyanide, 96-98 per cent.....lb.	.25 - .30	.32 - .35
Sodium fluoride.....lb.	.18 - .18	.19 - .20
Sodium hypochlorite (caustic soda).....100 lb.		6.50 - 7.50
Sodium hyposulphite.....lb.		3.03 - 3.04
Sodium molybdate.....lb.	2.50 - 3.25	3.25 - 4.00
Sodium nitrate.....100 lb.	3.00 - 3.25	3.75 - 4.00
Sodium nitrite.....lb.	.16 - .18	.19 - .20
Sodium peroxide, powdered.....lb.	.32 - .35	.35 - .40
Sodium phosphate, dibasic.....lb.	.03 - .04	.04 - .05
Sodium potassium tartrate (Rochelle salts) lb.		.39 - .40
Sodium prussiate, yellow.....lb.	.23 - .27	.31 - .32
Sodium silicate, solution (40 deg.).....lb.	.01 - .01	.02 - .02
Sodium silicate, solution (60 deg.).....lb.	.02 - .03	.04 - .05
Sodium sulphate, crystals (Glauber's salt) cwt.	1.60 - 1.70	1.75 - 2.50
Sodium sulphide, crystal, 60-62 percent (conc) lb.	.09 - .10	.10 - .11
Sodium sulphite, crystals.....lb.	.03 - .04	.04 - .06
Strontium nitrate, powdered.....lb.	.17 - .18	.19 - .20
Sulphur chloride red.....lb.	.08 - .09	.10 - .10
Sulphur, crude.....ton	25.00 - 30.00	
Sulphur dioxide, liquid, cylinders.....lb.	.09 - .10	.10 - .12
Sulphur (sublimed), flour.....100 lb.		3.80 - 4.35
Sulphur, roll (brimstone).....100 lb.		3.40 - 3.90
Tin chloride (stannous).....lb.	.42 - .44	.45 - .46
Tin oxide.....lb.		.16 - .20
Zinc carbonate, precipitate.....lb.	.16 - .18	.19 - .20
Zinc chloride, gran.....lb.	.13 - .13	.13 - .17
Zinc cyanide.....lb.	.45 - .49	.50 - .60
Zinc dust.....lb.	.11 - .12	.13 - .15
Zinc oxide, U. S. P.....lb.	.10 - .13	
Zinc sulphate.....lb.	.03 - .03	.04 - .06

Coal-Tar Products

NOTE - The following prices are for original packages in large quantities:

Alpha naphthol, crude.....lb.	\$1.40 - \$1.50
Alpha naphthol, refined.....lb.	1.60 - 1.70
Alpha naphthylamine.....lb.	.53 - .55
Aniline oil, drums extra.....lb.	.34 - .36
Aniline salts.....lb.	.41 - .45
Anthracene, 80% in drums (100 lb.).....lb.	.90 - 1.00
Benzaldehyde (f.f.c.).....lb.	2.00 - 2.10
Benzidine, base.....lb.	1.35 - 1.40
Benzidine, sulphate.....lb.	1.15 - 1.25
Benzole acid, U. S. P.....lb.	.90 - 1.00
Benzoate of soda, U. S. P.....lb.	.80 - .90
Benzol, pure, water-white, in drums (100 lb.).....gal.	.35 - .40
Benzol, 90% in drums (100 lb.).....gal.	.33 - .38
Benzyl chloride, 95-97%, refined.....lb.	.35 - .40
Benzyl chloride, tech.....lb.	.25 - .35
Beta naphthol benzoate (nominal).....lb.	3.50 - 4.00
Beta naphthol, sublimed (nominal).....lb.	
Beta naphthol, tech (nominal).....lb.	.80 - .88
Beta naphthylamine, sublimed.....lb.	2.25 - 2.40
Cresol, U. S. P., in drums (100 lb.).....lb.	.18 - .19
Ortho-cresol, in drums (100 lb.).....lb.	.23 - .25
Cresylic acid, 97-99%, straw color, in drums.....gal.	1.05 - 1.15
Cresylic acid, 95-97%, dark, in drums.....gal.	1.00 - 1.05
Cresylic acid, 50%, first quality, drums.....gal.	.65 - .75
Dichlorobenzol.....lb.	.08 - .10
Dimethylaniline.....lb.	1.50 - 1.60
Dimethylaniline.....lb.	1.35 - 1.45
Dinitrobenzol.....lb.	.30 - .37
Dinitrochlorbenzol.....lb.	.32 - .35
Dinitronaphthalene.....lb.	.45 - .55
Dinitrophenol.....lb.	.40 - .45
Dinitrotoluol.....lb.	.40 - .45
Dip oil, 25% tar acids, car lots, in drums.....gal.	.34 - .40
Diphenylamine (nominal).....lb.	.80 - .85
Fl-acid (nominal).....lb.	2.25 - 2.50
Metaphenylenediamine.....lb.	1.23 - 1.30
Monochlorobenzol.....lb.	.18 - .20
Monothylaniline.....lb.	2.00 - 2.40
Naphthalene crushed, in bbls. (250 lb.).....lb.	
Naphthalene, flake.....lb.	.19 - .19
Naphthalene, balls.....lb.	.19 - .19
Naphthionic acid, crude.....lb.	.75 - .85
Nitrobenzol.....lb.	.14 - .19
Nitro-naphthalene.....lb.	.40 - .50
Nitro-toluol.....lb.	.18 - .25
Ortho-amidophenol.....lb.	3.25 - 4.25
Ortho-dichlorobenzol.....lb.	.15 - .20
Ortho-nitro-phenol.....lb.	.80 - 1.25
Ortho-nitro-toluol.....lb.	.25 - .40
Ortho-toluidine.....lb.	.35 - .45
Para-amidophenol, base.....lb.	2.50 - 3.00
Para-amidophenol, HCl.....lb.	2.50 - 3.00
Para-dichlorobenzol.....lb.	.08 - .12
Paranitraniline.....lb.	1.40 - 1.50

Para-nitro-toluol.....lb.	\$01.35 - \$01.50
Paraphenylenediamine.....lb.	2.50 - 2.75
Paratoluidine.....lb.	2.00 - 2.50
Phthalic anhydride.....lb.	.65 - .75
Phenol, U. S. P., drums (dest.), (240 lb.).....lb.	.12 - .20
Pyridin.....gal.	2.00 - 3.50
Resorcin, technical.....lb.	4.25 - 4.50
Resorcin, pure.....lb.	6.25 - 6.50
Salicylic acid, tech., in bbls. (110 lb.).....lb.	.50 - .60
Salicylic acid, U. S. P.....lb.	.50 - .60
Salol.....lb.	.90 - 1.00
Solvent naphtha, water-white, in drums, 100 gal.....gal.	.33 - .35
Solvent naphtha, crude, heavy, in drums, 100 gal.....gal.	.23 - .26
Sulphanilic acid, crude.....lb.	.32 - .35
Toluidine.....lb.	1.70 - 2.50
Toluidine, mixed.....lb.	.45 - .55
Toluol, in tank cars.....gal.	.35 - .40
Toluol, in drums.....lb.	.38 - .40
Xylidine, drums, 100 gal.....lb.	.50 - .65
Xylol, pure, in drums.....gal.	.37 - .45
Xylol, pure, in tank cars.....gal.	.35 - .45
Xylol, commercial, in drums, 100 gal.....gal.	.37 - .45
Xylol, commercial, in tank cars.....gal.	.23 - .27

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark.....lb.	\$0.36 - \$0.39
Beeswax, refined, light.....lb.	.39 - .40
Beeswax, white pure.....lb.	.63 - .68
Carnauba, No. 1, (nominal).....lb.	1.00 - 1.05
Carnauba, No. 2, regular (nominal).....lb.	.85 - .88
Carnauba, No. 3, North Country.....lb.	.36 - .37
Japan.....lb.	.19 - .19
Montan, crude.....lb.	.23 - .25
Paraffine waxes, crude match wax (white) 105-110 m.p.....lb.	.09 - .09
Paraffine waxes, crude, scale 124-126 m.p.....lb.	.09 - .10
Paraffine waxes, refined, 118-120 m.p.....lb.	.11 - .12
Paraffine waxes, refined, 128-130 m.p.....lb.	.14 - .15
Paraffine waxes, refined, 133-135 m.p.....lb.	.16 - .17
Paraffine waxes, refined, 135-137 m.p.....lb.	.17 - .18
Stearic acid, single pressed.....lb.	.25 - .26
Stearic acid, double pressed.....lb.	.26 - .27
Stearic acid, triple pressed.....lb.	.27 - .28

NOTE - Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940.....gal.	\$1.80
Pine oil, pure, dest. dist.....gal.	1.60
Pine tar oil, ref., sp. gr. 1.025-1.035.....gal.	.48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank car f.o.b. Jacksonville, Fla.....gal.	.35
Pine tar oil, double ref., sp. gr. 0.965-0.990.....gal.	.85
Pine tar, ref., thin, sp. gr. 1.080-1.060.....gal.	.76
Turpentine, crude, sp. gr. 0.900-0.970.....gal.	1.75
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990.....gal.	.35
Pinewood creosote, ref.....gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.....280 lb.	\$12.25 - \$16.00
Rosin E-I.....280 lb.	16.10 - 17.25
Rosin K-N.....280 lb.	16.25 - 17.15
Rosin W. (G.-W. W.).....280 lb.	15.50 - 16.70
Wood rosin, bbl.....280 lb.	15.00 - 15.50
Spirita of turpentine.....gal.	1.58 - 1.58
Wood turpentine, steam dist.....gal.	
Wood turpentine, dest. dist.....gal.	
Pine tar pitch, bbl.....200 lb.	8.50 - 8.50
Tar, kiln burned, bbl. (500 lb.).....bbl.	14.50 - 15.00
Retort tar, bbl.....500 lb.	15.00 - 15.50
Rosin oil, first run.....gal.	.67 - .67
Rosin oil, second run.....gal.	.70 - .70
Rosin oil, third run.....gal.	.87 - .87

Solvents

73-76 deg., steel bbls. (85 lb.).....gal.	\$0.40
70-72 deg., steel bbls. (85 lb.).....gal.	.38
68-70 deg., steel bbls. (85 lb.).....gal.	.37
V. M. and P. naphtha, steel bbls. (85 lb.).....gal.	.29

Crude Rubber

Para-Upriver fine.....lb.	\$0.34 - \$0.35
Upriver coarse.....lb.	.24 - .24
Upriver caucho ball.....lb.	.26 - .26
Plantation - First latex crepe.....lb.	.32 - .33
Libbed smoked sheets.....lb.	.33 - .33
Brown crepe, thin, clean.....lb.	.32 - .32
Amber crepe No. 1.....lb.	.35 - .35

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.....lb.	\$0.17 - \$0.18
Castor oil, AA, in bbls.....lb.	.19 - .19
China wood oil, in bbls.....lb.	.16 - .16
Cocunut oil, Ceylon grade, in bbls.....lb.	.18 - .18
Cocunut oil, Ceylon grade, in bbls (nominal).....lb.	.16 - .16
Care oil, crude, in bbls.....lb.	.16 - .16
Cottonseed oil, crude (f.o.b. mill).....lb.	.10 - .11
Cottonseed oil, summer yellow.....lb.	.18 - .19
Cottonseed oil, winter yellow.....lb.	.21 - .22
Linseed oil, raw, car lots (domestic).....gal.	1.10 - 1.10
Linseed oil, raw, tank cars (domestic).....gal.	1.30 - 1.30
Linseed oil, boiled, car lots (domestic).....gal.	1.35 - 1.35

Olive oil, commercial.....	gal.	3 75	—
Palm, Lagos.....	lb.	10 1/2	11
Palm, bright red.....	lb.	10	10 1/2
Palm, Niger.....	lb.	11	12
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	13	15
Peanut oil, refined, in bbls.....	lb.	22	24
Rapeseed oil, refined in bbls.....	gal.	1 70	1 72
Rapeseed oil, blown, in bbls.....	gal.	1 80	1 85
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	16	16 1/2
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	10 1/2	11

FISH

Winter pressed Menhaden.....	gal.	\$1 17	\$1 18
Yellow bleached Menhaden.....	gal.	1 20	1 22
White bleached Menhaden.....	gal.	1 23	1 24
Blown Menhaden.....	gal.	1 30	1 32

Miscellaneous Materials

All f. o. b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.	net ton	\$22 00	25 00
Barytes, ground, off color, f.o.b. Kings Creek	net ton	18 00	20 00
Barytes, crude, 88% to 94% ba., Kings Creek	net ton	8 00	10 00
Barytes, ground, white, f.o.b. Cartersville, Ga.	net ton	23 00	25 00
Barytes, ground, off-color, f.o.b. Cartersville	net ton	16 00	19 00
Barytes, crude, 88% to 94% ba., Cartersville	net ton	12 00	14 00

Talc, powdered, Southern, f.o.b. cars.....	ton	12 00	15 00
Talc, imported.....	ton	60 00	70 00
Talc, California Talcum Powder grade.....	ton	20 00	35 00

Refractories

Chrome brick, f.o.b. Chester, Pa., carlots.....	net ton	90	100
Chrome brick, 9-in. str. and sizes, f.o.b. Baltimore.....	net ton	80	90
Fire clay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	45	53
Fire clay brick, 1st quality, f.o.b. St. Louis.....	1,000	45	—
Fire clay brick, 1st quality, f.o.b. New Jersey.....	1,000	75	—
Fire clay brick, 2d quality, 9-in. shapes f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	40	—
Magnesite brick, 9 in. straight, f.o.b. Baltimore.....	net ton	90	—
Magnesite brick, 9-in. sizes and shapes larger than 9-in.	net ton	90	100
Magnesite brick, f.o.b. Chester.....	net ton	55	—
Silica brick, 9-in. and 9-in. sizes, Chicago district.....	1,000	51	55
Silica brick, f.o.b. Birmingham.....	1,000	51	55
Silica brick, f.o.b. Mt. Union, Pa.....	1,000	50	55

Ferro-Alloys

All f.o.b. Works

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.....	net ton	200.00	\$250.000
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon, carlots.....	lb.	19	22
Ferro-chrome, per lb. of Cr. contained, 4-6% carbon, carlots.....	lb.	20	21
Ferro-manganese, 76-80% Mn.....	gross ton	190 00	225 00
Spiegel, 18-22% Mn.....	gross ton	75 00	—
Ferro-molybdenum, 50-60% Mo, per lb. of Mo.....	lb.	2 50	3 00
Ferro-silicon, 10-15%.....	gross ton	60 00	65 00
Ferro-silicon, 50%.....	gross ton	80 00	90 00
Ferro-silicon, 75%.....	gross ton	150 00	160 00
Ferro-tungsten, 70-80%, per lb. of contained W.....	lb.	1 10	1 15
Ferro-uranium, 55-50% of U, per lb. of U content.....	lb.	7 00	—
Ferro-vanadium, 30-40% of U, per lb. of contained V.....	lb.	6 50	7 75

Ores and Semi-finished Products

All f.o.b. Mines, Unless Otherwise Stated

Chrome ore, Calif. concentrates, 50% min.....	unit	60	65
Cr ₂ O ₃	unit	70	85
Chrome ore, 40%, min., Cr ₂ O ₃ , f.o.b. Atlantic seaboard.....	unit	18 00	19 00
*Coke, foundry, f.o.b. ovens.....	net ton	17 50	18 50
*Coke, furnace, f.o.b. ovens.....	net ton	24 00	—
*Coke, petroleum, refinery, Atlantic seaboard.....	net ton	17 50	—
Fluor spar, lump, f.o.b. Tonuco, New Mexico.....	net ton	—	25 00
Fluor spar, standard, domestic washed gravel.....	net ton	—	25 00
Kentucky and Illinois mines.....	net ton	—	25 00
Ilmenite, 52% TiO ₂ per lb. ore.....	unit	85	90
Manganese Ore, 50% Mn, c. f. Atlantic seaboard.....	gross ton	75 00	85 00
Manganese ore, chemical (MnO ₂).....	lb.	1 00	—
Molybdenite, 85% MoS ₂ , per lb. of MoS ₂	unit	42 00	—

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Connecticut

NAUGATUCK—The Naugatuck Chemical Co. will soon award the contract for the construction of a 4-story, 60x80-ft. plant addition. Estimated cost, \$75,000. Lockwood, Greene & Co., Federal St., Boston, engrs.

STAMFORD—The Perfection Enameling & Painting Co., Main and Grove Sts., plans to build a 3-story, 100x125-ft. manufacturing building.

Illinois

BUCKLEY—The Bd. Educ. plans to build a 1-story, 82x115-ft. high school. An experimental laboratory will be installed in same. Estimated cost, \$65,000. J. N. Coleman, 6257 St. Lawrence Ave., Chicago, archt.

CHICAGO—The Great Western Smelting & Refining Co., 600 West 41st St., plans to build a smelting plant consisting of three large 1-story units and an office building on Union Ave. and 51st St. Estimated cost, \$1,000,000. Henry L. Newhouse, 4630 Prairie Ave., archt.

Indiana

PORTLAND—The Portland Oil & Refining Co. plans to build a refinery. H. J. McConoley, secy. and treas.

Iowa

BAYARD—The Consolidated School Dist. is building a 2-story, 75x187-ft. grade and high school here. A chemical and physical laboratory will be installed in same. Estimated cost, \$180,000.

IOWA CITY—The State Bd. Educ. plans to build a library and chemistry building at the University of Iowa. Estimated cost, \$2,000,000. W. H. Bates, secy.

OTTUMWA—The Bd. Educ. is having plans prepared for the construction of a 3-story high school here. Chemical laboratories will be installed in same. Estimated cost, \$700,000. Croft & Boerner, 833 Palace Bldg., Minneapolis, archts.

WOODWARD—The city rejected all bids for the construction of a disposal plant here. Estimated cost, \$25,000. M. I. Evinger, Davidson Bldg., Des Moines, engr.

Kansas

PAOLA—The city has awarded the contract for furnishing filters to the Pittsburgh Filter Co., 429 Rialto Bldg., Kansas City, Mo., at \$10,900.

Kentucky

LOUISVILLE—The Dixie Belle Refining Co., 701 Inter Saw Bldg., is receiving bids for the construction of a refinery on Western Parkway. Estimated cost, \$500,000. C. B. Haun, archt. Noted July 7, 1920.

Massachusetts

CAMBRIDGE—The city is having preliminary plans prepared for the construction of a filtration plant. Estimated cost, \$600,000. Johnson & Benham, 150 Nassau St., New York City, engrs.

EAST EVERETT—The Boston Varnish Co. will soon receive bids for an addition to the varnish manufacturing building here. Estimated cost, \$30,000. Charles L. Betton, 31 Exchange St., Lynn, archt.

SPRINGFIELD—The Brightwood Brass Fdry., 365 Birnie Ave., will build a 1- and 1½-story, 52x72-ft. foundry addition. Estimated cost, \$15,000. Work will be done by day labor. Noted May 19.

SPRINGFIELD—The Davitt Iron Fdry., 191 Liberty St., will build a 1- and 2-story, 55x105-ft. foundry. Estimated cost, \$15,000. Work will be done by day labor.

WATERTOWN—Lockwood, Greene & Co., archts., 60 Federal St., Boston, will soon receive bids for the construction of a

1-story, 200x230-ft. foundry at the plant for the Walker & Pratt Mfg. Co., 31 Union St., Boston.

WORCESTER—The Worcester Pressed Steel Co., Barber Ave., will build a 2-story plant addition. Estimated cost, \$25,000. Work will be done by day labor.

Michigan

KALAMAZOO—The Bd. Educ. plans to construct a junior high school. A small chemical laboratory will be installed in same. R. A. LeRoy, 122 Pratt Bldg., archt.

Minnesota

MINNEAPOLIS—The Bd. Educ. will soon receive bids for the construction of a 4-story, 220x300-ft. senior high school on 20th Ave., N. E. and Quincy St. A chemical and physical laboratory will be installed in same. Estimated cost, \$700,000. E. H. Binger, 3018 Third Ave., S., archt.

RENVILLE—The Bd. Educ. will receive bids about Aug. 15 for the construction of a 2-story, 146x273-ft. high and grade school. A chemical laboratory will be installed in same. Estimated cost, \$280,000. Croft & Boerner, 833 Palace Bldg., Minneapolis, archts. Noted May 19.

New Jersey

SHILOH—The School Bd. of Hopewell Twp., care of W. S. Garrison, Roadstown, plans to build a 2-story, 60x122-ft. high school addition on Salem Bridgeton Rd. A chemical laboratory will be installed in same. Estimated cost, \$90,000. H. A. Hill, Broad St. Bank Bldg., Trenton, archt.

New York

LONG ISLAND CITY—The Stein Hall & Co., Inc., 61 Eway, New York City, has awarded the contract for the construction of a 4-story factory on 6th St. and Jackson Ave. to the Turner Constr. Co., 244 Madison Ave., New York City. Estimated cost, \$400,000.

WEST POINT Congress, Wash., D. C., appropriated \$18,000 for labor and material for the construction of a new dry cleaning, sterilizing and disinfecting building at the Military Academy here and \$12,000 for the purchase and installation of machinery and equipment in same.

Ohio

CINCINNATI—Readings, Panzer & Martin, archts., Palace Theatre Bldg., will soon award the contract for the construction of a 1-story, 100x157-ft. chemical warehouse on Dana Ave. for the E. K. Shannon Chemical Co., Dana Ave. and the Cincinnati, Lebanon & Northern R.R.

EATON—The city plans to construct a filtration plant for the local waterworks including filters, etc. Estimated cost, \$27,500.

LIMA—The city is having preliminary plans prepared for the construction of a sewage disposal plant, etc. Estimated cost, \$1,000,000. Fuller & McClintock, 170 Eway, New York City, engrs.

South Dakota

MITCHELL—The Sisters of the Presentation Order will soon receive bids for the construction of a 3-story, 40x160-ft. hospital. A chemical laboratory will be installed in same. Estimated cost, \$125,000. Edwin H. Lundie, 530 Endicott Bldg., St. Paul, archt.

Virginia

HARRISONBURG—The city plans to construct a 3,000,000-gal. filtration plant, etc. Estimated cost, \$500,000. Roberts Eng. Co., Charleston, W. Va., engr.

Quebec

LEVIS—The Levis Pulp & Paper Co. will receive bids until Aug. 1 for the construction of a 100-ton pulp mill on St. Romuald Rd. Estimated cost, \$500,000. G. Breakey, Breakeyville-Levis, engr.

MONTREAL—The Standard Iron & Chemical Co., 524 Ambrose St., will soon receive bids for a 4-story addition to its plant here. Estimated cost, \$100,000.

Ontario

BELL RIVER—The Fraser & Bryson Lumber Co., Ltd., Castle Bldg., Ottawa, will soon receive bids for the construction of a ground wood pulp mill. Estimated cost, \$300,000.

CHATHAM—The city is having plans prepared for the construction of a pump-house including mechanical sand filters, etc. Estimated cost, \$50,000. E. A. James Co., 36 Toronto St., Toronto, engr.

FORT WILLIAM—John G. Sutherland, archt., Dayton, O., will receive bids until Aug. 1 for the construction of a pulp and paper mill at the mouth of the Mission River, for the Fort William Pulp & Paper Co., Ltd. Estimated cost, \$1,000,000.

KINCARDINE—The Town Council will receive bids about Aug. 2 for the construction of a filtration plant. Estimated cost, \$15,000. Mr. Dallyn, Parliament Bldg., Toronto, engr.

PORT ARTHUR—The Nipigon Fibre & Paper Mills, Ltd., will receive bids until Aug. 15 for the construction of a 40-ton pulp mill in the Nipigon Dist. Estimated cost, \$200,000. J. A. Little, engr.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its 1920 meeting Dec. 27, 1920, to Jan. 1, 1921, at Chicago, Illinois.

AMERICAN CERAMIC SOCIETY will hold its summer meeting at the La Salle Hotel in Chicago, Aug. 16, 17 and 18.

AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Chicago, Sept. 7 to 10 inclusive.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in the Hotel Statler, Cleveland, Ohio, Sept. 30, Oct. 1 and 2.

AMERICAN FOUNDRYMEN'S ASSOCIATION will meet in Columbus, Ohio, Oct. 4 to 8 inclusive.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its one hundred and twenty-second meeting Aug. 20 to Sept. 3, at Lake Superior.

AMERICAN MINING CONGRESS will hold its next convention in Denver Nov. 15.

AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

AMERICAN STEEL TREATERS' SOCIETY, Chicago, will hold its second annual convention and exhibit, combined with the convention of the Steel Treating Research Society of Detroit, Mich., in the Coliseum Museum, Philadelphia, Pa., Sept. 14 to 18 inclusive.

ASSOCIATION OF IRON AND STEEL ELECTRICAL ENGINEERS will hold its 14th annual convention at the Hotel Pennsylvania, New York City, Sept. 20 to 24, 1920.

ENGINEERING COUNCIL will hold its next meeting in Chicago, Thursday, Oct. 21, 1920.

INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

IRON AND STEEL INSTITUTE (British) will hold its autumn meeting at Cardiff by invitation of the Ironmasters and Steel Manufacturers of South Wales and Monmouthshire. The date of the meeting will be Tuesday, Sept. 21, for the assembling of the members at Cardiff, and the formal proceedings will open on the morning of Wednesday, Sept. 22.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SIXTH) will be held in the Grand Central Palace, New York City, Sept. 20 to 25.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall national convention at Carnegie Music Hall, Pittsburgh, Pa., Nov. 10, 11 and 12, 1920.

TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its fall meeting at Saratoga Springs, N. Y., Sept. 1, 2 and 3.

Number 4

Co-ordinating Chemical Conventions in 1921

AN EXCELLENT suggestion relative to a group of chemical meetings in the fall of 1921 is made by Dr. HERTY in the July issue of the *Journal of Industrial and Engineering Chemistry*. It appears that four events are scheduled in which chemists generally will be interested. The British Society of Chemical Industry will come to this country for the first time in many years. The Canadian Institute of Chemistry, the American Chemical Society and the National Exposition of Chemical Industries will also hold their customary conventions. These events will prove so attractive that many chemists will undoubtedly wish to attend all of them, but will find it impossible to do so unless the meetings are held at approximately the same time.

The suggestion is that the four organizations co-ordinate their plans and hold a two-weeks' meeting—during the Exposition and immediately following. This would give ample time for the programs of the three technical societies and for inspection of the exhibits at the Exposition. More than this, it would give an opportunity to create closer professional relations among British, Canadian and American chemists and would strengthen Anglo-Saxon as well as professional bonds.

Subsequent to the war there was much talk touching on the probable Anglo-Saxon supremacy in world affairs. To such a prospect we have always given hearty assent and have welcomed every opportunity to promote its accomplishment. Consequently in this group of chemical conventions we see an opportunity to forward Anglo-Saxon unity and solidarity as well as chemical knowledge. The Chemical Exposition being a fixed festival, it would seem appropriate for its promoters to take the initiative in an attempt to realize this very delightful prospect.

Chemists in Public Life

WHEN the President appointed Dr. BOGERT as a member of the Tariff Commission, chemists generally welcomed the action as tangible evidence of the appreciation of the important part which a chemist could play in such an organization. Although Dr. BOGERT found it impossible to accept the appointment, there is no doubt that the profession should be represented on this important board, which bears such a vital relation to chemical industry. It is to be hoped that a chemist will yet be found to take the post.

Another evidence that the chemist is participating in public affairs is noted in the nomination of Dr. E. F. LADD as North Dakota's Republican candidate for the Senate. Dr. LADD is a chemist, having previously

been professor of chemistry in the North Dakota Agricultural College, of which he is now president. Without knowing to what extent Dr. LADD may represent the socialistic ideas of the Non-Partisan League of his state, we may nevertheless express the hope that, if elected, he will bring to bear on public affairs a mind trained in that kind of straight thinking which is developed by scientific education. When Dr. LADD's example is multiplied several fold, we can begin to look for benevolent effects in modifying the views of lawyers and professional politicians.

The I.C.C. Rivals Pandora

WHEN the Interstate Commerce Commission started a series of priorities for coal it opened a box of troubles for this country which makes Pandora's box of fairy fame seem quite insignificant. To be sure, coal is fundamental to all industries and a shortage of coal is perhaps as serious a matter as can readily be imagined for any community, but the cure chosen by the I.C.C. bids fair to establish more problems demanding immediate attention than a dozen such commissions can care for. In fact, it seems likely the disease would be preferred to the cure which has been devised.

Recently it was reported that all Japan was experiencing a financial disturbance approximating panic simply because of the collapse in the silk market. Here it was a dominating industry upsetting all the rest. In this country we seem in a fair way to establish a similar period of hard times by the collapse of transportation facilities resulting from excessive diversion of freight cars into coal traffic.

More serious even than this industrial disturbance is the possibility of direct hazard to whole communities which are just now reporting that they cannot even get the necessary chemicals for water purification. Such a situation, involving contaminated city water, would be even more serious than temporary fuel shortages for our vital public utility concerns.

Not only are important chemical supplies being thus disturbed, but essential road building is altogether interrupted, construction work is at a standstill and we are in a fair way toward hard times for much of our industrial fabric simply because raw materials are not available and the product of our factories cannot be moved from the storeroom. All this, too, is the more regretted when there is certainly some question as to whether there has actually been any general serious coal famine threatening in this country this year.

The total quantity of fuel required in the United States is rather accurately known. We have had shortages in production below the average estimated requirements, and locally throughout the country there have

been deficiencies in supply that threaten interruption of gas, electric and street railway service and industrial activity of less direct public importance. However, the method chosen to correct this difficulty seems to have resulted simply in a topsy-turvy industrial situation.

Unfortunately the tremendous powers of the I.C.C. under the 1920 transportation act have been used simply to give cars for coal movement. There seems to be no machinery available, certainly none actively in motion, for the elimination of unnecessary fuel uses or the increase of efficiency of fuel utilization. Either of these two limitations would doubtless be adequate if means for their accomplishment had been available. It is time for the technical man to give thought to these matters, especially to the question of increasing the work done per pound of fuel supply. It is a problem of greatest national concern and one to tax the ingenuity of our most clever engineers and chemists.

Study of Failures

The Road to Perfection

DEFFECTIVE metal furnishes a fascinating field for metallurgical investigation—gripping the huntsman instinct in the searcher and rewarding him with information of utmost importance to one really striving for reliability in manufactured products. Human life so often depends upon stanch reliability, yet every now and then a failure occurs in such a most mystifying way that the onlooker is apt to exclaim, "A plague on all your pseudo-science!" Yet why should a new cast-steel bridge seat suddenly fail at a critical moment, precipitating a whole span into the river, although under lower stress than it withstood many times during erection? Who can convince his fellow of the real reason for the epidemic of flakes, as soon as Americans tried to make gun forgings in quantity? Why are transverse fissures in rails, where do they originate, and how can they be avoided? Until such questions as these are answered, metallurgists are far from that ideal which they should hold in common with physicians: "Each ailment must be susceptible of accurate diagnosis." This is evidently prerequisite to the ultimate goal of "preventive medicine."

One naturally likes to talk more about his successes than his failures, even though he is taught far more by one shortcoming than by a hundred victories. The metallurgist will point with pride to the tremendous tonnage which fulfills its expected service in a satisfactory, if not an unexceptional, manner, far rather than dwell upon the faulty material which also slips through. Here is the very trouble! A defective heat, or a defective ingot, or a defective beam, bar, rail or rod may exert its influence so subtly as to be unobserved and only recognized so long after the event that the details of its manufacture cannot be recovered—in fact, it was apparently made under exactly the same conditions as its predecessors and successors, all acceptable.

It is only natural that the steel maker should blame the service to which his metal has been put, and that the user should blame the manufacturing processes. Both periods in the piece's history are so very intricate that usually it has been impossible to locate the exact trouble—at least so far. But this "passing the buck" gets absolutely nowhere. Progress certainly

would result should we all adopt Dr. GIOLITTI's suggestion, made on page 149 of this issue, that each destructive abnormality, or even suggestive observation, should be recorded immediately with all possible collateral evidence, and then given the widest publicity. Successful manufacturing processes are so extraordinarily complex that systematic research designed to synthesize a correct procedure is well-nigh impossible. Evidently greater hope lies in the study of a great mass of data on individual occurrences which are known to affect the quality of the product. **CHEMICAL & METALLURGICAL ENGINEERING** welcomes such material, believing firmly that along this road lies success in the effort to make good metal better.

A Noteworthy Case of University Industrial Research

IT HAS been but a year since the evaporator experiment station at the University of Michigan was completely equipped, but in that brief space of time investigations of a fundamental character have been made in the phenomena of heat transfer. The actual factors entering into industrial operation are being sought out and intimately studied one by one. The investigators have the advantage of being in the proper environment. They are away from the multitude of interferences such as the plant investigator invariably has to contend with. They can be autocrats, for the evaporating equipment is to serve them and their work only.

In the end they will deduce practical theories on evaporation and evaporator design which at present rest almost wholly on a pure-science basis, without cognizance of many practical factors. The student chemical engineer who undertakes an investigation under these conditions has quite as much incentive for work as his brother chemist in the research laboratory. He will not be frittering his time away on a toy machine with no more satisfaction than a child gets out of his electric train. And when he finishes his work he will hold rank in accordance with his academic accomplishments. If he is endowed with tact and other natural qualities, he can advance rapidly in an organization that has use for his kind of special training.

Full-sized steam plants have been part of the equipment of almost every institution where mechanical engineering is taught. It would be too much to expect every department of chemical engineering to follow this example and erect full-sized equipment in adequate variety to offer as complete facilities as are given in mechanical engineering. On the other hand, might it not be possible for different institutions to emphasize certain operations, and equip their laboratories accordingly?

For post-graduate work, at least, this plan would offer excellent facilities. There is much to be said both for and against full-sized equipment in school laboratories. It is seldom necessary for purposes of instruction only, but where industrial investigations are to be made, it may be impossible to interpret results gained in any other than large-scale apparatus. The Michigan example is an interesting one and should be suggestive to other institutions where chemical engineering is taught and where the lead may be taken in at least one field of industrial research.

Ceramists' Dream Of the Future

IF YOU will wander, some fine day, out into the hills with the geologist, he may point to this and that example of differential weathering on the rocks and say: "It took ten million years for these few inches of rock to wear away, or one hundred million years to erode that gully." All of which, aside from giving you the impression that our historians have been remiss in recording the total period of world existence, will prove that natural silicates stand the weather pretty well. Then if you sit right down on the hillside and think about it out there in the clear sunshine, there may come a real dream of the greater part that ceramic materials must play in our future structures, and how the eroded dust of these rocks lying in clay beds on the plain below may be re-covered and re-formed to rocks with wearing characteristics equal to the natural product.

The clay worker may exceed the works of nature as regards refractoriness and strength and fabrication to any shape until the day will come that even the metals will be displaced in some of the useful arts, and the ceramist comes into his own at last.

Obstacles to Prosperity

PROSPERITY and progress, when applied to a people, are almost synonymous terms. No difficulty should be experienced in distinguishing from mere activity. Business can be very active without there being real prosperity or actual progress. Men may be working hard all day without being efficient and without producing lasting and useful results. It is easier to have business activity, merely as activity, than to have the kind of activity that makes for prosperity and progress.

These remarks are intended to have a particular bearing on the subject of new construction. A certain amount of construction is needed to make up for natural depreciation, and a certain amount in addition is needed for progress. Of late there has been much more activity than progress or true prosperity. In particular there has been little new construction.

There are four major obstacles, or difficulties, in the way of construction work, those that represent an investment intended to yield annual returns as well as eventual replacement of the principal. There are: (1) High interest rates for capital. (2) Indifferent performance of workmen. (3) Poor rail transportation service. (4) Unreasonable prices.

High interest rates for capital are naturally a deterrent to investment construction, since they offer the investor another form of investment. We are in a little danger just now, by the way, of getting a fallacious idea as to interest rates, for it has been contended seriously in some quarters of late that since both wages and commodity prices have gone up the interest rate ought to go up too. The misleading expression "cost of capital" is used. There is really no comparison, for capital goes by an interest expressed in percentage. One would not argue that, in the case of a factory, a larger percentage of the income should be used to buy raw materials than before the war, a larger percentage should be used to pay wages and a larger percentage should be left for profit, for the total can be only 100 per cent. If capital does command an unusually high

percentage rate, that is merely an indication that there is something unsound, and a serious deterrent to construction work is furnished.

As to the performance of workmen, the barrier or obstacle may not be as great as is often supposed. Performance is a relative matter, moreover, and when one considers the making of an investment that involves the employment of labor he must compare present labor efficiency with prospective efficiency, not past efficiency.

The poor rail transportation service now furnished is a great obstacle to construction work, for various materials must be assembled, and if one is lacking, the whole work suffers and the cost of the job is increased.

In calling unreasonable prices the fourth obstacle to construction work the word "unreasonable" is used advisedly. For a few months after the Armistice there was much arguing that we had inflation of various sorts, hence prices would have to be high, but there have been great divergences. It is not reasonable that some prices should be double their pre-war average, others triple, and still others up only 50 per cent. Granting that the average is right, some prices are too high and some are too low. The investor can see these discrepancies and naturally concludes that while everything may not be wrong, some things are wrong, and he is disposed to wait until there is a better balanced price structure.

The Industrial Nurse As an Asset to Industry

NURSES are beginning to appear in industrial establishments, and the reports of them are generally favorable. Where plants are isolated and the workers live in company houses or in proximity to the works, there is the same need for the industrial nurse that there is for a district nurse in any community. Under such circumstances she is a regular visiting nurse whose business is to temper mercy with judgment; yet always to abound in mercy; to be part doctor, part priest, part lawyer, all nurse and then some more. She must be singular in her very multiplicity of qualities. The right woman on the job has a nose for trouble in its brewing, does not tell tales, has the confidence of everyone and knows how and when to give advice to all sorts and conditions of men and women. Her price is above rubies. And the wrong woman on the job can cause more trouble than a brimstone match.

In other establishments, no matter how centrally located, such nurses are engaged to be on call in the works during business hours. Not only where women are employed but also among men she knows just how to handle minor accidents, how to patch and bind up fingers, to look after sanitation, to make a gentle fuss if things get foul anywhere and to give good advice to grown up, strong, burly children. Then, too, in case of a major accident, she knows just what to do until the doctor comes, and also when to send for the doctor, which is an art in itself. She has a keen eye for septic conditions even in little scratches, and under workmen's compensation laws her precautions often save large sums of money as well as fingers and hands and arms or toes and legs and even lives. There is a National Organization for Public Health Nursing, with headquarters in Cleveland, Ohio, that is providing special training for nurses in the industrial field. The work is useful and the women are needed.

Western Chemical & Metallurgical Field

Company Reports

ANACONDA COPPER MINING CO.

Though the year 1919 was one of uncertainty in the non-ferrous metal industries and one of reduced production, the Anaconda Copper Mining Co. has retained its organization and taken advantage of the curtailment of operations to carry out extensive improvements in the mines at Butte, to continue and largely complete construction under way at the various plants and to advance, without interruption, the South American undertakings. Definite steps have also been taken in enlarging the company's field of activity.

The smoke treatment plant at Anaconda, consisting of twenty Cottrell treater units, was put into commission during the year and has demonstrated its efficiency. A special reverberatory furnace with Cottrell treaters was also completed for smelting the dust from the main treaters and satisfactory recovery of the copper, silver, gold and arsenic is obtained. Construction of an arsenic refining plant of 400 tons monthly capacity was begun and partially completed and when finished will refine the arsenical dust from the treaters on the special reverberatory.

An experimental 25-ton tower acid plant has been constructed and its operation demonstrated this new system of producing sulphuric acid to be an unqualified success. This type plant will be used in connection with the production of acid for the treatment of phosphate rock at Anaconda. The erection of an experimental plant to produce about thirty-five tons of a product containing 48 per cent of soluble phosphoric acid was begun. The product is to be marketed under the name of "Treble Acid Phosphate." To supply the phosphate rock a deposit near Garrison, Mont., was acquired and development work undertaken. The right to purchase a large deposit of high-grade phosphate rock in Caribou County, Idaho, has been acquired. About 25,000,000 tons of rock can be mined from this deposit through tunnels. Plans have been made to install the necessary machinery and townsite facilities to begin active operations.

An additional rotary converter was installed at the Great Falls electrolytic zinc plant substation in order to have a spare unit when operating the plant at full capacity.

A plant for the production of white lead made by an electrolytic process is being erected at East Chicago, Ind., adjacent to the plant of the International Lead Refining Co. This plant will be operated by the Anaconda Lead Products Co.

Considerable development work has been carried on in South America by the Andes Copper Mining Co. More than 12,000 feet of churn drilling has added 33,000,000 tons to the reserves, making a total of 120,000,000 tons of ore having a copper content of 1.48 per cent developed. Work on the main water supply and on the townsite has progressed satisfactorily. The Potrerillos railway was completed in May, 1919. General drawings of the reduction works have been completed and a pilot plant, located at the mines, has been put in operation. In

this working unit tests are being conducted and the problems which arise in the application of the process are being worked out.

CONSOLIDATED MINING & SMELTING CO. OF CANADA, LTD.

The plant at Trail is becoming an increasingly important factor in the development of the natural resources as well as in the industrial expansion of western Canada. Various departments have been enlarged, new departments have been added and marked progress has been made in the recoveries of metals and in the concentration of ores during the past year. The present electrolytic copper refinery has a capacity of twenty tons of refined copper per day. This is being increased to fifty tons per day capacity to take care of the production of the Canada Copper Corp. A copper rod mill of the same capacity is being built. Improvements in the efficiency of the electrolytic lead refinery have reduced the cost of producing lead by this method below that of a Parkes process plant operating on the same tonnage. The gold and silver refinery has been practically rebuilt and is now thoroughly up to date. A new method of concentrating the ores from the Sullivan mine has been developed which consists of low-temperature roasting and wet magnetic separation; the concentrator has been recently completed. This will result in decreasing the cost of producing electrolytic zinc by providing a more satisfactory product for the plant. The sulphuric, hydrofluoric and hydrofluorsilicic acid plants are in satisfactory operating condition. A flotation mill of 200 tons daily capacity was run for several months on Rossland ore and its operation proved that this can be concentrated at reasonable cost and with good recoveries. A 1,500-ton mill is planned.

The company is expanding its activities particularly with the idea of increasing the production of copper and with this end in view has acquired controlling interests in the Coast Copper Co. and the Sunlock Mines, both on Vancouver Island.

Production for fifteen months ended Dec. 31, 1919, was: Gold 59,605 and silver 1,782,025 oz.; lead 41,711,147, copper 6,933,962 and zinc 30,743,461 lb.

Water Power Act Regulations Being Drafted

Regulations to be used in carrying the Water Power Act into effect are being drafted by Oscar C. Merrill, the executive secretary of the Federal Power Commission; General Enoch H. Crowder, representing the War Department, and Herman Stabler, representing the Interior Department.

Applications for permits under the new act now approximate 1,000,000 hp.

Lieutenant Colonel William Kelly of the Engineer Corps has been appointed by the President to serve with the Power Commission as Engineer Officer. Much of Colonel Kelly's experience in the Engineer Corps has been in California, where he has been brought in contact with water power problems. He was in France with the 117th Engineers.

COCONUT GROVE

Philippine Industrial Material, Products and Resources Available to the United States

A Review of the Greatly Diversified Agricultural, Mineral and Other Resources in the Philippine Islands, and the Opportunities to Increase Their Supply — Manufacturing Possibilities and Advantages of Locally Developed Industries

By DR. ALVIN J. COX*

THE people of the United States have been so busy with their own affairs and the development of their own natural resources that they have given too little time to the study of their neighbors and trade possibilities on the Pacific. San Francisco, which could best handle and make use of the raw materials from Pacific Coast tributary countries for manufacturing development, especially on account of her location and climate in which work can be carried on uninterruptedly throughout the year, has been insufficiently active; and California generally has been so interested in agriculture that it has given much too little thought to industrial achievement.

Information concerning Philippine commercial and industrial possibilities has been given out periodically in the United States, but at no time has received the attention it warranted. The Philippines is not a foreign country, but is under the flag of the United States, and, while not an integral part of the United States, her judicial tribunal is maintained under American auspices, a condition which greatly facilitates business transactions with this country. The Philippine Government is doing everything possible to improve its harbor and docking facilities by the construction of additional piers, coal and oil depots, etc., to accommodate shipping. The mercantile and financial interests of the United States, including manufacturing, agriculture, shipbuilding, the export and import business, oil, mining and timber industries, transportation and public service interests, etc., should awake to Philippine possibilities.

The development of the Philippines will be an important asset to the section of the country accomplishing it

and large profit will accrue not only to the business concerns directly interested but also the business community generally in attracting, centralizing, facilitating and increasing industrial and economic trade development. In my opinion the United States should bid especially for the foreign raw materials and business of the nations and their dependencies of the Pacific, and particularly for those products of the Philippine Islands suitable for export.

Many products now made from imported Philippine raw materials could be produced more cheaply there and the finished product imported, thus relieving our labor shortage. Exporters must join the importers in any development drive, for it should be realized that money spent there goes into a country where it is to our advantage to increase the purchasing power of each resident, for that increase largely will be spent for the purchase of American manufactured materials, if we adapt our methods to the needs and desires of the customers. Furthermore, by buying raw materials in the Philippine Islands, we are building up a line of supply that will not be interrupted by European wars. Why not build up a dependable supply not subject to those interrupting conditions?

AGRICULTURAL PRODUCTS

The Philippine Islands at no time have produced sufficient rice for local consumption, preferring, or finding it more profitable, to bring forth their well-known agricultural export products, such as abacá (Manila hemp), tobacco, coconuts and sugar cane, which always afford an excellent investment. With the shortage of binder materials during the last few years the producer of abacá has reaped a particularly valuable harvest. Even in ordinary times the supply of abacá

*Director, Philippine Bureau of Science, 1912-19.

is insufficient and the plant is peculiar in that it cannot be grown elsewhere than in the Philippine Islands. It is believed that there will be a shortage for many years to come; for that reason the U. S. Bureau of Agriculture is endeavoring, by a special representative, to stimulate the production of sisal and maguey as a secondary Philippine supply. Many of the tobacco lands of the world have been turned to the production of essential food crops. Although tobacco was profitable before the war, the prices are now much higher, and probably will continue so for several years. The dried meat of the coconut is marketed for the production of oil. Coconut oil yields more glycerine than any other similar substance and has found an excellent market during the war period. However, coconuts will prove to be an exceptionally valuable crop at any time, for there is less likelihood of finding a chemical substitute for coconut oil than for any other Philippine product.

The exports of sugar from the Philippines in 1918 exceeded those in 1917 by more than 147,400,000 lb. During the last year there has been a great stimulus in the construction of sugar centrals, but even yet the production by native methods of the much less profitable raw sugar greatly exceeds that of centrifugal sugar. Many regions in the Philippines are ideally suited to the growing of sugar cane and on account of the great profit the production of sugar by modern methods will continually increase. Abacá, tobacco, coconuts and sugar cane largely have export markets. In 1918, there were exported 374,000,000 lb. of abacá, 360,000,000 cigars and 57,200,000 lb. tobacco in other forms. Also there were exported 121,000,000 lb. of copra (dried coconut meat), 253,000,000 lb. of coconut oil, 140,800,000 lb. of centrifugal sugar and 462,000,000 lb. of raw sugar. These had a value of about \$59,000,000, \$7,000,000, \$6,000,000, \$5,000,000, \$31,500,000, \$6,000,000 and \$10,000,000 respectively.

Although there has been an unusually large increase in the exports of abacá, tobacco, coconuts and sugar cane since American occupation of the Philippines, still there is under-production and the cultivation of each can with profit be greatly increased. There is every evidence that the selling price of these products will continue at a fairly high level for years to come, particularly in view of the increased uses and the utilization of what formerly was waste product. For many months the copra market has been steady with a price more than three times that at which it formerly was profitably produced.

Besides the multiplication of these well-established products there is a wealth of natural and industrial possibilities that it is the purpose briefly to discuss here.

PHILIPPINE ALCOHOL AND BEVERAGES

There is a shortage of alcohol for industrial purposes, partly due to diminished production. The curtailment of consumption by the enactment of prohibition laws has not equalled the increased industrial demand. There are three of the cheapest sources of alcohol in the Philippines—namely, discard molasses from sugar-cane mills, tuba (sap) from the flower stem of the nipa palm and possibly from the coconut palm, and starch from the starch plants. Almost the entire insular production, about 10,000,000 proof gallons per annum, is made from the tube of the nipa palm. This palm grows wild in tidewater swamps. There are large areas of nipa-palm swamps that have not been developed. The collection of discard molasses is now difficult, owing to the production

of sugar in many small mills; but when central mills are in general use, about 7,000,000 gal., capable of producing 5,000,000 proof gallons of alcohol, will be available annually. The growing of starch plants for the production of alcohol is very encouraging. Both cassava and arrowroot give much better yields and are just as easy to handle as ordinary potatoes, which have been found to be a cheap source of alcohol in continental Europe. With development, the Philippines practically could obtain a monopoly of the alcohol industry.

Most of the alcohol at present produced in the Philippine Islands is used locally for fermented drinks. Distilled spirits from the fermented sap of nipa and coconut palms, stored for five years in casks, are named "Philippine coco palm brandy" and "Philippine nipa palm brandy." Analyses made by the Bureau of Science show that these products conform to the requirements of good brandy.

PALM SUGAR

Excellent sugar has been made from the sap of several palms, but the product is absorbed by the local markets. The buri palm is too scattered to be a great commercial source, but the nipa palm, which grows in immense areas on tide land in various parts of the Philippine Islands and yields a sap which is now the source of alcohol, is available. Nipa sap has a composition similar to that of the juice of sugar cane and it can be used more profitably for the production of sugar than for alcohol. There are large areas of nipa swamp that have never been developed. The fronds are used for thatch.

COCONUT SHELLS AND CHARCOAL

Coconut shells were not exported in large quantities before the declaration of war, although scientists long have used them for producing high gas-absorption-power charcoal. In 1918 more than \$500,000 worth of coconut shells and \$125,000 worth of coconut-shell charcoal were exported. It is hoped that this industry so nicely started may be maintained. Charcoal also has been made from mangrove wood and lumbang and pili shells, with a view to determining the efficiency of charcoals made from materials available in commercial quantities in the Philippine Islands. Results indicate that pili-nut-shell charcoal has a higher gas-absorption power than any other charcoal made.

PHILIPPINE FIBERS AND BINDER MATERIALS

Abacá, besides being exported as such, is used in the rapidly growing Philippine cordage industry. Frequently maguey and other fibers are cheaper than abacá, and they are as satisfactory for many cordage purposes. In 1918 the cordage exports amounted to more than \$1,100,000.

The fiber extracted from the petioles of the buri palm is used for making buntal hats, which are marketed in the United States as Bangkok hats. The buntal hat is one of the best hats of the Philippine Islands. Fine hats made from bamboo fibers are marketed under the name of Batavia hats. Several fibers are used in the manufacture of high-grade hats similar to Panama hats. Hats made from buri palm leaves are cheaper and better than the cheaper hats sold in the United States. Abacá affords an abundant supply of excellent raw material which is woven into women's hats.

The commercial rattans of the Philippine Islands are derived from the climbing palms. The many species in the Philippine Islands belong to three genera. The stripped material of some species is very tough; it has great tensile strength, does not break easily in bending, and can readily be bleached. There is no reason why a considerable export trade in Philippine rattans should not be developed.

There are various species of trees and certain small shrubs represented in the Philippine Islands that have between the wood and the bark a tough fibrous layer known as bast fibers. These have extensive local use as substitutes for abacá.

Coconut husks yield a valuable fiber known as coir. In the Philippines a new and profitable industry can be established by using coir for the manufacture of brushes, ropes, doormats, etc. In the coir industry, all the processes employed are simple, and machinery need not necessarily be used. In beating out the fibers two classes result—the coarse brittle fiber averaging 12 in. in length and the finer mattress fiber. The latter may be spun into coir yarn. One thousand coconuts will produce from 66 to 77 lb. of brittle fiber and about 308 lb. of mattress fiber.

True cotton is cultivated and made into various articles for local use. Pineapple fiber and some of the above-enumerated fibers are manufactured into cloth for which there is a certain export demand. Cloth known as piña, made from the pineapple fiber, is similar to very fine linen, and is used especially in making fine embroidery. Sinamay, made from abacá, is similar to crinoline and is used for similar purposes. The so-called Ilocano cloth, made from cotton, has a characteristic weave and coloring and is popular for curtains, pillow covers, etc.

Tree cotton, kapok, while of too short a fiber to be of use as textile material, is a superior filling for pillows and mattresses. The fibers are oily and, therefore, do not become easily water soaked. For this reason kapok is a suitable filler for life preservers, life jackets, etc.

RESINS, TERPENES, PERFUMES, EDIBLE NUTS AND VEGETABLE OILS OTHER THAN COCONUT OIL

Elemi, balao, apitong, almáciga and copal find application in the varnish industry, and in the making of resin soaps. The essential oils of ylang-ylang, champaca, vetiver, lemon grass, orange, cinnamon and ginger are used in the perfume industry, and several of them are used in the manufacture of non-alcoholic beverages and fruit flavors.

The pili nut is very delicious and has a flavor similar to that of the Brazil nut. It is very rich in oil.

Important vegetable oils are produced in the Philippine Islands from the physic nut, peanut and pili nut, and from the seeds of lumbang, kapok, cato, cashew, castor bean and cotton. Lumbang oil has good drying qualities and is used in the varnish and linoleum trades. The Indian variety of castor bean grown in the Philippines gives a high oil content. Cultivation is simple and does not involve so much actual work as does the growing of other staple crops, and returns are certain.

COMMERCIAL PLANT PRODUCTS

Coffee grows well in several parts of the Philippine Islands, and beans of excellent quality are produced, especially in the highlands of Luzon. Scientific cultivation is probably necessary to increase the output.

First-class cacao is grown to limited extent in many localities, and the production could be readily increased to export proportions.

Papaya gum of as great activity as the best on the market has been and can be produced in the Philippines, and offers an industry new to the islands.

Strychnine can be extracted from the seeds of *Strychnos ignatii*, a plant indigenous to the Philippines.

The leaves and the seeds of *Datura alba*, which grows wild in the Philippines, are valuable as an asthma remedy and for other medicinal purposes.

Several species of Philippine plants yield a high percentage of starch. The most promising of these are cassava, or camoting cahoy (*Manihot utilissima pohl*), and tapioca. Among other possible sources of starch are arrowroot (*Maranta arundinacea linn.*), sincamas (*Pachyrhizus erosus urban*), the Polynesian arrowroot (*Tacca pinnatifida forst.*), yams (*Dioscorea*), the seeds of *Cycas circinalis linn.* and the sugar palm (*Arenga saccharifera labill.*).

Natural vegetable dyes are used locally. More than \$400,000 worth of sapan wood was exported in 1918.

RUBBER AND GUTTA-PERCHA

The indigenous Philippine rubber-producing plants are vines and are scarcely adapted to cultivation. The cultivated rubber trees, the plants that produce so-called para, ceara and castilloa rubbers are, without exception, native of tropical America. All of these species have been introduced into the Philippines and do exceedingly well. In 1917 I was shown 7-yr.-old para trees on a plantation near Isabela de Basilan that were said to yield 2.25 kg. of rubber per tree per year. The *Castilloa elastica*, a tree native of Mexico, seems adapted to the Philippine Islands because it is not attacked by wild hogs. There have been some remarkable rubber yields from 4-yr.-old trees of this species. Castilloa is given no cultivation and is frequently planted in a new clearing. The cultivation of rubber trees on a large scale will probably prove eminently successful in those parts of the Philippines outside of the typhoon belt, where there is a uniformly distributed rainfall—that is, in southern Mindanao and the Sulu Archipelago.

LUMBER, TANBARK AND LEATHER

An entire bureau of the Philippine Government is devoted to forestry and is in charge of forest administration. The virgin forests of the Philippines cover more than 40,000 square miles, and in addition there are about 20,000 square miles of second growth forests. The principal virgin forests are dominated by trees of the *Dipterocarp* family, and the stand of these may be estimated roughly at 18,000 board feet per acre, although several times this amount is not unusual. Practically all the timber belongs to, and is administered by, the government. At present there are about thirty-seven sawmills operating in the Philippine Islands, of which six cut over 25,000 board feet per day and five from 12,000 to 20,000 board feet per day. The total cut of the mills of the Philippine Islands in 1918 was about 70,000,000 board feet. There are large quantities of timber in the Philippines suitable for interior finish, furniture, cabinet wood, heavy construction and for special uses. A supply of timber for almost any purpose is readily available.

The area of the mangrove swamps of the Philippine Islands is estimated to be 511,500 acres. The bark

FIGS. 10 TO 17

Fig. 15. Native sugar-cane mill in operation. Fig. 16. Filipino women making buntal hats. Fig. 17. Filipino preparing rattan for use in making chairs.

from the mangrove yields an excellent tanning material. Cutch, the evaporated water-extract of tanbark, is imported into the United States in large quantities. This is extensively used in tanning leather, and is supposed to be the basis of khaki dye. The value of tanning materials imported into the United States is nearly \$2,000,000 per annum and tanners are becoming each year more dependent upon imported material. Bark from the better species of Philippine mangrove trees contains 30 per cent of tannin. A net profit of from \$25 to \$30 per ton can probably be made on tanning material derived from the mangrove swamps in the Philippine Islands. Piles, firewood and the products of wood distillation could be made in connection with the cutch industry. The bark of Benguet pine and of palo maria can be also utilized as tanning materials. Forest regulations prevent the cutting of palo maria exclusively for its bark. The scope and possibilities of the tanning industry in the Philippine Islands may be inferred from the fact that about \$2,500,000 worth of leather is used annually. More than half of this demand is met by importation. In 1918 more than \$2,000,000 worth of leather and manufactures thereof were imported into the Philippine Islands. Some high-grade leather is produced locally, and there is no reason why the entire supply should not be produced in the islands.

PAPER PULP

One of the bamboos, known as *cana bqio*, has been shown to be especially suitable for the making of paper pulp; it grows in sufficiently large and pure stands to make possible the commercial production of paper pulp. Abacá waste, cogon, talahib, rice straw, etc., are other materials from which the Bureau of Science has made strong paper pulp and which it should be possible to utilize commercially for the same purpose. There is a Philippine law authorizing a bonus for the establishment of a paper-pulp factory in the Philippine Islands.

INSECT PRODUCTS

Wild bees are plentiful in all of the wooded portions of the Philippines. There is a considerable local trade in excellent honey and wax, which are collected by the crudest methods. Apiculture with domesticated bees should be developed. It could be carried on in connection with farming to the extent of excluding imported honey, and the pollination of all plants would be improved.

The Bureau of Science has introduced silkworms into the Philippine Islands, and has developed a hybrid which has nine generations yearly. The worms do well in the Philippines. Their food, the mulberry, grows most luxuriantly in all part of the islands and is free from pests. An acre or 440 trees will feed about 3,000,000 silkworms per annum, and the leaves may be harvested two years after the cuttings have been planted. There is an excellent market for all the silk that can be produced.

SEA PRODUCTS

Among the marine products that have commercial possibilities are trepang (*beche de mer*), tortoise shell, top-shell (*trochus*) and other button shells, pearl and pearl shells, window shells, sponges, shark fins, edible seaweed, isinglass, crocodile skins, sardines and other sea fishes, etc.

The trepang industry could be spread readily to various northern islands, although now the catch is con-

fined almost wholly to the Sulu Islands. About \$500,000 worth of turban and top-shells were marketed during 1918 and certain of the Manila button factories were forced to close due to the scarcity of shells. It is believed that there are many untouched beds of these shells that might easily be exploited. The pearling industry is well established in the southern part of the Philippine Archipelago. Window shells are used locally in the place of window glass. They can be made into attractive screens and lampshades. The collection of sponges in Philippine waters is comparatively a new industry. The elephant's ear sponge collected in the territorial waters is of great value. The export of shark fins amounted to \$60,000 in 1918, and this could be greatly increased. Practically all the marine products could be greatly increased.

Sardines are found in Manila Bay and in certain other localities in the Philippine Islands in abundant quantities, sufficient to warrant the establishment of canneries. In addition to the true sardines, there are large numbers of small clupeoid fishes (small herring) which are allowed to be labeled "Sardines." There are found in the Philippines the tuna and a number of other fishes, such as the Spanish mackerel or king fish, Japanese mackerel and several species of the pampango family, that are well adapted to canning purposes. Coconut oil, which is manufactured in the Philippine Islands, could be used for a local sardine product, for the temperature everywhere is above the solidification point of the oil. Olive oil and soya-bean oil for this purpose should cost about the same as in the United States. There are large quantities of peanuts grown in the Philippine Islands, and some of the oil companies plan to manufacture the oil, so this too might be available for canning purposes. The Filipinos prefer their sardines in tomato sauce. Tomatoes grow well in the islands, and this would be the cheapest material to use. Salt is produced locally in quantity from sea water. With this opportunity and these advantages for the establishment of a cannery in the Philippine Islands, \$2,500,000 worth of fish and fish products were imported in 1918 simply because no one had taken the initial action in starting this new industry.

MINERALS, METALLIC AND NON-METALLIC

The production of gold steadily increased from 1910 to 1916, when a value of \$1,408,320 was marketed. The output in 1917 was \$1,059,500. Silver is found alloyed with gold in practically all of the gold deposits, in the ratio of one part silver to four parts gold. Silver is found associated with galena in Bulacan, Paracale, Mindanao and Marinduque. There are said to be extensive deposits of comparatively pure galena on the latter island. Copper deposits are known to exist in Batangas, Pangasinan and Benguet Provinces; Mountain Province, Mindoro, Masbate, Panay and Mindanao. Some of these have been worked for years. There are several valuable deposits of iron ore in the Philippines and some of them are exceedingly well located for economic handling of the ore. An unworked laterite iron-ore deposit in Surigao, Mindanao, has been estimated to contain over 500,000,000 tons of available ore, averaging approximately 50 per cent iron. Manganese occurs as psilomelan, pyrolusite and wad in Ilocos Norte, Pangasinan, Bulacan, Tarlac and Masbate. Several thousand tons of manganese have been shipped in the last few years.

Petroleum is known to occur in Luzon, Cebu, Iloilo, Capiz and Leyte Provinces, and in Mindanao Island.

The bogs of Bondoc Peninsula, Tayabas Province, Luzon, have been especially studied, and are believed to be worthy of exploration by drilling. The oil has a paraffine base and is practically free from sulphur. Commercial quantities of asphaltic materials and bituminous limestone exist in Leyte.

Coal to the value of \$2,330,000 was imported into the Philippine Islands in 1918. Almost every island in the Philippine Archipelago and the majority of the provinces are known to contain coal or lignite, and some of these deposits are now being developed and mined.

Desirable raw materials for the manufacture of portland cement occur in the Philippine Islands. Some of these are adjacent to undeveloped coal fields, the fuel from which is suitable for burning cement. Excellent coralline and crystalline limestones suitable for the manufacture of lime occur throughout the archipelago. Asbestiform minerals are widespread in the Philippines. Bat guano occurs in caves in nearly every province. Salt to the value of \$250,000 is each year manufactured in the Philippine Islands by evaporating sea water by solar heat. The Philippines also contain mineral resources of fireclay, abrasives, sulphur, stone and artesian and mineral waters, etc.

The principal manufactured products of the Philippine Islands are coconut and other oils, soap, tobacco products, cordage, hats, fertilizer ingredients, buttons, tanned products, embroideries, woven articles, matches, etc. The Rizal Cement Co. has a small modern plant at Binangonan. However, the imports of cement in 1918 were \$498,500.

The lime heretofore produced in the Philippine Islands is of inferior quality, and much of that used for sugar manufacture and for other chemical purposes has been imported. The increased production of sugar by modern methods has so augmented the demand for lime that there is now a need for the output of large kilns. The price would be sufficient to insure a handsome profit for good lime. Hydrated lime should find extensive use for road-building and for waterproofing concrete. In the sixteenth annual report of the Director of the Bureau of Science for the year ended Dec 31, 1917, I pointed out that in lime, sand-lime brick, salt, caustic soda, bleaching powder and chloroform there is a group of allied industries that should be successfully operated together in the Philippine Islands. The success of a caustic-soda plant depends rather on the development of local consumption than on its produc-

FIGS. 18 TO 22

Fig. 18. Native abaca press, Albay Province. Fig. 19. Hauling sugar cane (bull carabao). Fig. 20. Wild bees in Cementerio del Norte, Manila. Fig. 21. Cano boho, especially suitable for making paper pulp. Fig. 22. Calumbagan sawmill, Mindanao.

tion for export; and, in addition to utilizing it in the manufacture of soap, thus increasing the consumption, a paper factory and glass industry should be developed. Each of the latter presents an excellent opportunity. The experiments in the Bureau of Science in glass making prove that bottles, demijohns, glass jars, drinking glasses, lamp chimneys, etc., of good quality can be manufactured of Philippine raw material, and the results obtained in the manufacture of paper from Philippine raw materials are also very encouraging.

Clay products and various byproducts from the ash of tobacco wastes, copra cake and other plant wastes present excellent opportunities. Byproducts which up to the present time are largely being wasted but which, if properly developed, may become a source of income to the islands are glycerine, molasses, bromine, iodine, tannin, bleaching powder, chloroform, acetic acid and its derivatives, wood alcohol and several other products derived from the dry distillation of wood, etc.

The Philippine industrial materials available to the United States are far greater than is generally understood to be the case. A few of these are now imported, but there are opportunities to increase the supply of these and develop others. The undeveloped ones and a large supply of all may be produced by engaging in attractive production enterprises in the Philippine Islands in addition to the utilization or importation of the raw materials. In all of the agricultural industries there are excellent commercial opportunities and there is a large amount of virgin fertile soil that could be cultivated.

Alizarine Dyes in South India

The following article regarding the supply and distribution of dyes in South India recently appeared in a Madras paper:

"It is well known that alizarine dyes were, prior to the war, imported mainly from Germany. In fact, out of 6,469,739 lb. of alizarine dyes imported into British India during 1913-14, as much as 4,637,450 lb. -- or 71.7 per cent of the total imports--came direct from Germany, and 804,143 lb. (probably of German origin) from Belgium. Imports from Germany during 1914-15 fell to about half the quantity of the previous year, dwindled to an insignificant quantity in 1915-16, and afterward stopped completely.

"On the outbreak of the war strenuous attempts were made by the British Alizarin Co. to increase its output, but not until the early part of 1918 was the company able to send to India any material quantity of dyestuffs. About April, 1918, advice was received from the British Alizarin Co. that it was shipping to its agents in Madras (Best & Co.) five tons of alizarine and that there was good prospect of regular supplies being received in future. The Board of Trade, however, required Best & Co. to certify in respect of each sale that the dye had been sold to a consumer and not to a dealer.

GOVERNMENT CO-OPERATION GRANTED

"To enable them to do this and to keep down the prices to a proper level, Best & Co. applied to the government for assistance and co-operation. In May, 1918, the government sanctioned the introduction of a scheme by which collectors of districts were asked to constitute local committees to deal with applications for dyes from bona fide dyers. The committees were to consist of two well-known dyers of the locality, with a government

official of standing as president of the committee. The applicant for dyes had to make a formal application, and if it was proved that he was a bona fide dyer he would receive a limited supply at a price fixed by the collector of the district. In the case of Madura alone, which is the chief dyeing center of Madras Presidency, an exception had to be made. The system of certificates was tried there for some time, but had to be given up owing to certain circumstances special to that place. Since October, 1919, the distribution of dyes at Madura has been left in the hands of Best & Co.

GERMAN REPARATION DYES--GOVERNMENT CONTROL OF PRICES

"According to the terms of the peace treaty, Germany is to deliver to the Allies a certain quantity of dyestuffs as part of the reparation for the injuries done to the Allied nations. Out of the German dyestuffs allotted to the British Empire, arrangements have been made to secure the whole of the reparation alizarine dyes for India in addition to a portion of the other reparation dyes. These supplies will be in addition to supplies which would, in any case, have been sent to India by the British Alizarin Co.

"The first consignment of German reparation alizarine dyes for Madras has now been received; it amounts to 200 casks of 4 cwt. each. This consignment and future consignments of alizarine dyes expected from this source will also be distributed in accordance with the scheme referred to above. The stock that has arrived has been allocated to the various agencies of Best & Co. The British Alizarin Co.'s new works at Manchester are expected to be completed by June next, and shortly afterward it expects to be able to supply the total Indian requirements from these factories. Meantime the arrangements detailed above will continue to be in force.

"In conclusion, it may be of interest to the public to know that Best & Co., the Madras agents of the British Alizarin Co., are not at liberty to charge any price they choose. The government fixes the price per pound and Best & Co. have to sell the dyes at that rate; they are allowed a fixed percentage as commission on the net proceeds after deducting duty and handling charges. The sale price of alizarine has now been fixed at 1 rupee 3 annas [38c.] per pound at any of Best & Co.'s depots.

Production of Indigo in Manchuria

The annual production of indigo in Manchuria approximates 4,000,000 to 5,000,000 lb., of which about one-third is disposed of in the Mukden market, reports Consul General Albert W. Pontious. The best quality sold there in May at 26c. per 1½ lb., and the cheaper grades at 15c. and 21c. In favorable soil the yield per fifteen acres is estimated at from 20,000 to 25,000 lb. of leaves, from which about 533 lb. of crude indigo is obtainable. Previous to the war foreign artificial indigo was imported into the Mukden consular district to the extent of approximately \$700,000, and into the whole of China to the extent of \$5,500,000 annually. The increasing price of artificial indigo subsequent to the elimination of Germany as a source of supply has made the vegetable indigo industry very profitable again. While a small amount of the foreign indigo is still on sale, the price of \$170 per cask of about 175 lb. is practically prohibitive.

The Chemistry of the Brain

BY CLARENCE JAY WEST*

THE brain and nervous system control, either directly by nerve impulses or indirectly through the blood stream, the metabolism and activity of all the other tissues of the body. They are, therefore, the master tissue of the body." While the nervous tissue comprises a relatively small part of the entire body, its superior reactivity or irritability enables it to control or set the pace for the other tissues.

The chemistry and metabolism of the nervous tissue are from almost every point of view the most absorbing and interesting of the problems of physiological chemistry. Matthew in his textbook states that the whole of evolution is characterized by the steady development of the nervous system, and by the steady development of no other tissue. The power of adapting the organism to a changing environment has been solved by the development of a tissue of the body which should be most irritable, which should control the other tissues, and which, having memory, could profit by experience. It is by means of his nervous system, and in that respect alone, that man stands at the summit of the animal world.

In spite of the importance and fascination which this study should possess, we know comparatively little regarding the chemical composition of the brain and the properties of the substances which are characteristic of nervous tissue. Much of our present knowledge is due to Thudichum, who worked comparatively unknown and entirely unappreciated, owing to his unusually combative nature, for many years (about 1865 to 1875) in England. The results of his investigations were published in the form of reports during this period, and later were collected in the form of a book under the title "The Chemical Composition of the Brain of Man and Animals." Among the later investigators in this field we may mention Koch, Fränkel, Rosenheim, MacLean, Thierfelder and Levene.

Our methods for analyzing the proximate constituents of the brain are far from satisfactory at the present time because of the complexity of the material in question. The following figures represent in a rough way the composition of the gray and the white matter:

	Gray	White
Water	85.3	70.2
Protein	7.6	8.6
Lipoids	3.1	18.1
Water soluble	0.5	1.4

The composition of the solids of the human brain is given by Koch as follows, the figures being per cent of dry matter:

	Whole Brain (Child)	Whole Brain (Adult)	Corpus Callosum
Protein	46.6	37.1	27.1
Extractives	12.0	6.7	3.9
Ash	8.3	4.2	2.4
Phosphatide	24.2	27.3	31.0
Cerebrosides	6.9	13.6	18.0
Lipoid sulphur	0.1	0.3	0.5
Cholesterol	1.8	10.9	17.1

The protein material of the brain is of the same general composition and nature as that found in the other parts of the body. If there is anything characteristic about it, it is the presence of normal amino-caproic acid. This is a matter probably of not very great significance, and it is unlikely that this acid is found only in brain protein.

*Information Department, Arthur D. Little, Inc.

The characteristic property of nerve tissue which differentiates it from all other tissues of the body is the presence of a large amount of ether and alcohol soluble material, which has been called by the collective name lipoids. The scope of this term varies with various investigators, but in general it has been used to include cholesterol, the nitrogen-containing bodies and the nitrogen and phosphorus-containing bodies. It is probable that there also exists a sulphur-containing body in the brain, but whether it contains in addition only nitrogen or whether it contains both nitrogen and phosphorus has not been determined.

CLASSIFICATION OF KNOWN BRAIN SUBSTANCES

The following classification represents our present knowledge of the substances which have been definitely established. The literature of lipoids is very confusing, because names have been given to bodies which are mixtures of two or more of these, or which contain other impurities.

I. Cholesterol. Really this should not be classed as a lipid, and is included only because it occurs in the alcoholic extract of nervous tissue.

II. Cerebrins. (Nitrogen-containing).

a. Phrenosin.

b. Cerasin.

III. Phosphatides. (Nitrogen- and phosphorus-containing).

1. Ratio of N: P = 1:1.

a. Lecithin.

b. Cephalin.

2. Ratio of N: P = 2:1.

Sphingomyelin.

IV. Sulphur-containing compound.

Let us first consider the lipid materials by studying their methods of isolation. The fresh brain matter is carefully freed from the covering tissue, washed, ground in an ordinary meat grinder, and dried *in vacuo*. This drying is usually carried out at 95 to 100 deg. C. The dried material is then ground to a fine powder and thoroughly extracted with hot alcohol. This removes all of the lipid material, although as the process of purification continues a large part of it becomes insoluble in alcohol. Upon cooling the alcoholic extract, a large amount of the cholesterol and a certain amount of the nitrogen and nitrogen- and phosphorus-containing bodies separate out.

The filtrate will contain the greater part of the lecithin and cephalin. This is evaporated to dryness or to a thick sirup in vacuum and poured into acetone. This procedure precipitates all of the lipid material and is a means of separating this from the fats and cholesterol. Because of the solubility of the lipoids in one another, this lecithin mixture will contain a considerable amount of the cerebrins and some sphingomyelin. The latter are insoluble in ether, and, therefore, extraction with ether will remove the lecithin and cephalin. Cephalin is insoluble in alcohol, and by dissolving the lecithin-cephalin mixture in ether and pouring this solution into alcohol, we are able to effect a certain separation of lecithin and cephalin. The procedure is very tedious, but finally results in the preparation of a cephalin which is free from lecithin. The preparation of a pure lecithin involves a considerable amount of additional work.

The mixture of cerebrins and sphingomyelins may be separated by a complicated system of precipitation

and fractionation, involving the use of acetic acid, petroleum ether, alcohol, and pyridine. The details of this method have been worked out by Levene and will not be given here.

The sulphur-containing body is found in the same fraction as the cerebrins, and all attempts to obtain a product which is rich in sulphur or which is constant in composition have been unsuccessful.

We thus see that, in general, the lipid material may be separated into two groups, the solid, almost crystalline (cerebrins and sphingomyelins) and the sticky amorphous lecithin and cephalin. Without going too deeply into the organic chemistry of these bodies, let us look briefly into their chemical composition. Lecithin, which is probably the best known of all of these bodies, is a glyceride which contains one molecule of stearic acid, one molecule of an unsaturated acid, which probably belongs to the oleic acid series, while the third hydroxyl of the glycerol is esterified by means of phosphoric acid, which in turn carries a choline residue. That is, the lecithin molecule may be represented by the following formula:

Our knowledge of the chemistry of lecithin was greatly increased by the application of the principle of reduction with hydrogen and palladium, because by this reaction one is able to obtain a crystalline body. Upon hydrolysis of this crystalline lecithin we obtain only stearic acid. This, therefore, does away with the possibility which many investigators have thought probable, that lecithin was a mixture of a stearic acid and a palmitic acid glyceride.

The chemistry of cephalin is much more complicated. Thudichum, who first isolated this body, observed that the carbon content was approximately 60 per cent. The products of hydrolysis were found to be glycerol, stearic acid, an unsaturated acid probably of the linoleic series, phosphoric acid and amino-ethyl alcohol, $\text{NH}_2\text{CH}_2\text{CH}_2\text{OH}$. If the composition is calculated from these components, it is found that the carbon should be 66 per cent. Thudichum noticed this discrepancy between the observed and calculated values for carbon, but made no attempt to account for it. Later investigators likewise obtained a cephalin with 60 per cent of carbon, but no attempt was made to explain this difference until Levene started his work. Levene and West spent a year in attempting to so purify cephalin that the carbon content would be raised to 66 per cent, but without success. The attempt to reduce cephalin with hydrogen was at first unsuccessful, but lately reduced cephalin has been prepared. Various derivatives, especially urethanes, were prepared, but these were unsatisfactory because of their amorphous nature and threw no light on the composition of the body in question. Very recently Levene has been able to show that it is probable that during the process of purification there is a certain decomposition of the cephalin molecule and that one fatty acid radical is split off. Either this is the explanation or there occur in the

brain two cephalins, one of which contains two fatty acid residues, while the other contains only one.

The cerebrins are a much more satisfactory class of compounds as regards work in the laboratory. They crystallize readily from alcohol and other solvents. Here again we find that we are dealing with a mixture of two substances. By careful fractionation from a number of solvents one is able to obtain a more insoluble fraction, which is found to contain only cerebronic acid. Cerebronic acid is a hydroxy-acid which contains twenty-five carbon atoms, and which on oxidation yields lignoceric acid. Lignoceric acid is familiar to some of us because it has been isolated from the soil and from wood. The other components of this more insoluble fraction, which has been given the name phrenosin, are galactose and sphingosine. Galactose is of course a well-known sugar. Sphingosine has been shown to contain seventeen carbon atoms, two hydroxy groups and one amino group, together with an unsaturated bond. By oxidation of sphingosine it is shown that the unsaturated bond is between the thirteenth and fourteenth carbon atoms, since the product of oxidation was tridecylic acid. Upon reduction and subsequent oxidation pentadecylic acid was obtained. This indicates that the amino and hydroxyl groups are located on the last three carbon atoms. Various attempts have been made to prepare the unsubstituted amine from sphingosine in order to locate the relative positions of the hydroxyl and amino groups. These efforts have been unsuccessful thus far. It has generally been assumed that the amino group is on the last carbon atom, and we may, therefore, express the formula for sphingosine approximately as follows:

The more soluble fraction of cerebrin (cerasin) becomes richer in lignoceric acid as the process of purification proceeds, and since we find no other substance upon hydrolysis, we may assume that the only difference between phrenosin and cerasin is in the nature of the fatty acid. It is, of course, desirable that an absolutely pure cerasin containing 100 per cent of its acid as lignoceric acid should be isolated. We may write the general formula of these compounds as follows:

Upon hydrolysis of sphingomyelin we obtain the following products: Sphingosine, identical with that obtained from the cerebrins, choline, phosphoric acid, and a mixture of fatty acids, one of which is lignoceric acid. The other acid appears to have the composition of a hydroxy-stearic acid, but this is not definitely established because of the difficulty in obtaining this acid in a pure state. It is still an open question as to whether there are two sphingomyelins, one containing cerebronic acid and the other hydroxy-stearic acid, or whether the molecule is a diphosphatide containing both of the fatty acids mentioned.

It is thus seen that the chemistry of the lipoids offers

a large number of unsolved problems. The difficulties in the field are many. The materials are very similar in physical and chemical properties, and are particularly hard to separate because they are so nearly neutral in character. If there was an acid or a basic group from which to prepare characteristic derivatives the hope of separation should be infinitely greater. As it is, one is dependent entirely upon very slight differences in solubility in mixtures of organic solvents. The losses in these fractionations are very great, and it is only when we work with kilograms of the material that we can hope for any success. Even with all of these difficulties, the field is a fascinating one and still offers an opportunity for a real contribution to our knowledge of physiological chemistry.

The British China-Clay Industry

There are signs that the china-clay export trade of England is beginning to revive after the severe blow dealt it by the war and by the exchange and transport difficulties that have hindered its development since the armistice. No other country possesses deposits of china clay similar in character and essential qualities to those found in Cornwall and Devon, although the United States, Germany and Austria have developed their native white earths for use as a substitute for china clay in certain classes of goods. The total production of china clay in Great Britain before the war was approximately a million tons per annum, but the trade is capable of considerable expansion.

England is the only country that exports china clay, the white earths of other countries being in no demand outside their centers of origin, and only to a limited extent there. Roughly, two-thirds of the British trade is export. Of the total production of 964,000 tons in 1912 (the last normal year, 1913 having been the year of the clay strike) over 661,000 tons were exported. In 1917 the total production dropped to 508,152 tons and the export trade to 310,750 tons, while in 1918 the production dropped to 465,325 tons and the export to 232,464 tons. Last year the export rose to 286,543 tons. During the later months of the war the exports to Russia, Germany, Belgium, and the Netherlands, representing in 1914 over 177,000 tons, were wiped out, except for 1,000 tons in 1918, and the exports to America had dropped by more than half—from 320,000 tons in 1914 to 152,000 tons in 1918.

REGAINING OF AMERICAN AND EUROPEAN TRADE

The utilization of American kaolins by manufacturers of the United States has been artificially assisted through war-time freights inflating the price of English china clay, but with the gradual return of freights to normal the regaining of the American market by British clay shippers is only a matter of time. Recent big shipments seem to point to this being the case. As the American market accounts for nearly half of the normal china-clay export trade of the United Kingdom, and was actually more than half in 1914, it is important to the British industry that this business be recovered.

As to the European trade, here again the question of price may have a temporary influence against the recovery of some former markets, especially in countries which possess white earths capable of being used in certain classes of goods, but eventually the superior quality of English china clays will assert itself. Higher

production costs in labor and material have forced up china-clay prices to a figure to which exporters are making every effort to accustom their former customers, and the gradual rise in the export trade points to the success of their efforts.

CONTINENTAL STOCKS EXHAUSTED—THE HOME TRADE

The export trade has a lot of leeway to make up before it attains to the normal. In 1912 Russia took 45,000 tons, and there has yet to be recovered the pre-war trade of 94,000 tons to Germany, 67,000 tons to the Netherlands, 58,000 tons to Belgium, 45,000 tons to France, and 21,000 tons to Italy, let alone the 40,000 tons to other foreign countries and the 35,000 tons to British possessions. There is this encouraging feature—that all the stocks of china clay on the Continent are practically exhausted, and that the replacement of those stocks, apart from running supplies, must absorb large quantities in the very near future. [The annual exports of unmanufactured china clay from the United Kingdom to all countries since 1913 have totaled: 1913—629,703 tons, value \$3,617,902; 1914—628,620 tons, value \$3,677,585; 1915—333,964 tons, value \$2,085,709; 1916—393,893 tons, value \$2,567,069; 1917—310,750 tons, value \$2,339,078; 1918—232,464 tons, value \$2,258,786; and 1919—286,543 tons, value \$3,712,843. For the first three months of the present year the shipments amounted to 90,236 tons, valued at \$1,186,419.]

The home trade also reveals hopeful signs. With the paper mills going at full blast to overtake a large accumulation of unfilled orders, the potteries busily engaged in meeting big demands from abroad, the "boom" in the cotton-textile trade, and the requirements of the chemical trades—all of which industries use china clay at some stage of their work—there is every reason for anticipating a revival approaching pre-war dimensions in the china-clay trade of Great Britain this year.

Fire-Resistant Coatings for Wood*

Fire-retarding paints are the most practical means so far discovered by which small amounts of wood can economically be made fire resistant. The only other known methods of decreasing the flammability of wood are to keep it wet, or to inject into it certain chemicals under pressure. These methods, though more effective than painting, are usually either impracticable or too expensive to be considered.

Ordinary calcimine or whitewash has proved in tests to be as fire resistant as any paint covering tried. It is cheap and convenient to use. Although it will not prevent the burning of wood exposed continuously to a high heat, a good coat of calcimine on wood will decrease the danger of a blaze spreading from burning cigarettes, sparks, matches and similar small sources of fire. Calcimine is, of course, more effective for inside than for outside use.

For exterior use numerous patented fire-retardant paints are available. An effective outdoor paint which has been developed at the Forest Products Laboratory consists of linseed oil, zinc borate and chrome green. This paint has maintained its fire-resisting properties through more than three years of exposure to the weather.

*From Forest Products Laboratory Technical Notes, June, 1920.

New Regulations for the Importation of Dyestuffs, Drugs and Chemicals

THE War Trade Board section of the Department of State announces that General Import License PBF 57 (War Trade Board Ruling 825, issued Aug. 15, 1919) as revised and extended now permits the importation into the United States from all countries of the world without individual import licenses of all commodities excepting synthetic organic drugs, synthetic organic chemicals, dyestuffs, products derived directly or indirectly from coal tar, including crude and intermediate products and mixtures and compounds of such products. For the importation of the commodities for which individual import licenses will continue to be required, new regulations have been made, as follows:

All applications for licenses must be made in triplicate on Form M provided for the purpose. The rules and regulations must be complied with strictly.

DYESTUFFS FROM GERMANY

Licenses for the importation of dyestuffs of German make or origin similar kinds or satisfactory substitutes of which are unobtainable in the United States on reasonable terms as to price, quality and delivery may be granted in limited quantities for use of consumers to meet their own special manufacturing requirements, in conformity with special rules and requirements, as follows:

A letter stating clearly the requirements must accompany the application for license. Allocation certificates must be secured from the War Trade Board Section. On request special forms will be furnished consumers for application for allocation certificates, which when granted will entitle the consumer, on import application therefor to the War Trade Board Section, to licenses for the importation of such German dyestuffs as may be enumerated on the allocation certificates. Such certificates must be transmitted to the War Trade Board section with completed import applications (Form M) for licenses in order to receive attention. Allocation certificates, at the option of the consumer, may be indorsed over to an importer or other person to accomplish such importation, in which case the indorsee should complete and transmit import application (Form M) accompanied by corresponding allocation certificates to the War Trade Board section.

DYESTUFFS FROM NON-ENEMY SOURCES

Import application (Form M) for licenses for the importation of dyestuffs and for intermediates entering into the manufacture of dyestuffs of non-enemy manufacture must be confined to quantities not in excess of six months' manufacturing requirements and must be accompanied by affidavits or signed statements from ultimate consumers to the effect, if true, that the dyes, indicating them, in the quantities asked for are not in excess of their manufacturing requirements for a period of not exceeding six months from the date of receipt, and agreeing to notify the War Trade Board section of the date of their receipt. In completing import applications for licenses definite information must be furnished showing the name of the country in which the dyestuffs or the intermediates were produced and the name and address of the producers in order to have applications receive attention.

SYNTHETIC ORGANIC DRUGS AND CHEMICALS FROM GERMANY

Licenses are not being granted for the importation into the United States or its possessions of synthetic organic drugs or synthetic organic chemicals of German make or origin if the same drugs or chemicals or satisfactory substitutes are obtainable in sufficient quantities from domestic sources on reasonable terms as to price, quality and delivery to supply domestic requirements. Accordingly, applications for licenses for the importation of such commodities from Germany or of German make must show the chemical as well as the trade name, or the chemical character or composition, as may be, of each article, together with all other information available which will serve to aid in its identification, including the statement, if true, that the article or a satisfactory substitute for the purpose is unobtainable in the United States, or if obtainable, is unobtainable either in sufficient quantities or in required quality or at reasonable terms or delivery; further, that the quantity asked for is not in excess of six months' requirements for domestic consumption. Quantities of these commodities for consumption in manufacturing plants must be accompanied by affidavits or signed statements from the ultimate consumers along the lines indicated. Appropriate statements in accordance with the foregoing from three or more reputable physicians should accompany import applications for licenses for the importation of drugs and medicines of German make or origin.

SYNTHETIC ORGANIC DRUGS AND CHEMICALS FROM NON-ENEMY SOURCES

On receipt of import application (Form M), accompanied by appropriate statements that the quantities are not in excess of six months' requirements for their own use or for purposes of sale to the trade, consideration will be given the matter of granting licenses for the importation, in limited quantities aforesaid, of synthetic organic drugs and synthetic organic chemicals of non-enemy make. Definite information must be given in the import application showing the name of the country in which the drugs or chemicals are produced and the name of the producer abroad, together with the statement that no part of the goods are of German make or origin.

SHIPMENT OF CONTROLLED COMMODITIES PRIOR TO OBTAINING LICENSE

Licenses for the importation of controlled commodities should always be obtained in advance of placing orders, and failure so to do cannot be accepted as a valid reason for granting licenses for the importation of any such commodities through any waiver of the rules and regulations governing such importations.

NATIVE DRUGS AND CHEMICALS

Native drugs and chemicals in their earthy state, as mined or grown, and which have been subjected to no chemical treatment whatever, may now be imported into the United States from any country in the world without a license, the same as before the war, and no formalities are now necessary with the War Trade Board section in connection with the importation of such commodities.

Cracks in Ingots

A Demonstration That One Class of Deep-Seated Cracks Is Due to the Generation of Parasitic Centers of Crystallization in Undercooled Regions of the Melt, With the Result That Adjoining Phenocrysts Are of Widely Different Composition

By FEDERICO GIOLITTI

CRACKS in ingots and castings are the principal things to avoid in steel-casting practice. Without attempting to classify and discuss exhaustively the kinds of defects which appear from time to time, it is sufficient to point out that some of them result from purely chemical phenomena, which develop as a rule during furnace work, while others are caused by distinctly physical reactions ordinarily arising during solidification and cooling of the metal. Inclusions of slag and blow holes belong to the first category; surface and internal cracks, on the other hand, are more commonly thought of as being due to differential thermal expansion during cooling through the solidification and transformation range.

IMPORTANCE OF LOCAL UNDERCOOLING

These phenomena have been carefully studied, but only in a few cases have their exact causes been determined. Unfortunately, flaws and cracks, though of the greatest importance, have been almost exclusively ascribed to hypothetical "internal stresses." This point of view has been accepted with such faith that in many cases internal stresses or a fancied adhesion of ingot to mold has been said to cause surface cracks!

I am convinced that the phenomena of local undercooling and of segregation and their effect on intercrystalline adhesion are far more important than internal stresses in originating flaws in metal, which in turn render the forging or other working of large masses of steel so delicate. Since illustrative cases where defects can be definitely ascribed to certain particular causes are not frequently met with, I believe that it is important that every such instance should be given wide publicity. The following observations, therefore, previously printed in part in *L'Industria*, vol. 29, Nos. 16 and 17, refer to a special case, analogous to many others which have come under my observation, where the interrelation is especially clear between the process of crystallization,

its accompanying segregation, and surfaces of deficient strength in the steel.

DISCOVERY OF EXTENDED CRACKS

A 50-ton nickel-steel ingot of the following composition was cast from an acid open-hearth in an octagonal cast-iron mold.

C	0.36	S	0.002
Mn	0.69	P	0.024
Si	0.27	Ni	2.02

Before the ingot was completely cool, it was placed in a reheating furnace, then roughed in a press to a cylinder of diameter but little smaller than across flats, and the top and bottom cropped. Even this early in the history of the piece there appeared some of those baffling defects which certainly are not *exclusively* due to differential thermal expansions.

For instance, Fig. 1 shows a thin crust of considerable area which peeled off parallel to the bottom cut, curling out on itself, evidently indicative of a plane of little strength along the parting. Other such surfaces were later found in the same metal.

After rough pressing and cropping, a cylindrical core about 500 mm. diameter was cut longitudinally down the axis, which on removal was found to be broken in three parts by irregular cross-fractures. Splitting the end of the core along an axial plane gave a block whose intersection with the lower break is sketched in Fig. 2

Fig. 2. Sketch of crack across axial core from ingot shown in Fig. 1.

by the line *CDE*. A cross-cut *AB* then produced a sample for examination. After careful polishing and etching this surface for about 3 hr. in a 20 per cent H_2SO_4 solution at 60 deg. C., macrostructure of the portion shown cross-hatched in Fig. 2 immediately gave a clue to the cause of failure along an extension of plane *LD*.

Under eye examination, the most evident fact was the notable difference between the structure of part *ACDL* and part *LDHB*. In the left hand part clearly defined large dendrites were well developed, while on the right of *LD* a poorly defined granular structure existed, and the line *LD* itself was well marked by deep pits. All these characteristics were intensified by etching an hour longer, when the appearance was photographed in Fig. 3. Even further extended acid attack did not alter the essential appearance, but even emphasized the difference in structure and dug deeper into the metal at the common boundary.

Under microscopic examination, Fig. 4 shows the structure of the left-hand part, while Fig. 5 shows that of the granular structure immediately adjacent to the

FIG. 1. TRANSVERSE CRACK NEAR BOTTOM OF INGOT

FIG. 3. DIFFERENCE IN MACROSTRUCTURE IN ADJOINING PORTIONS OF INGOT

right (part LDHB) after repolishing and etching with at 5 per cent HNO₃ solution in amyl alcohol. The contrast between the relative areas occupied by ferrite and pearlite is extreme. Chemical analysis confirmed the fact that carbon was lower in the right-hand phenocryst, and that the average metal as tapped from the furnace was intermediate:

	Mass ACCL (Dendritic)	Analysis of Heat	Mass LDHB (Granular)
C	0.44	0.36	0.30
Si	0.26	0.27	0.24
Mn	0.70	0.69	0.62
P	0.034	0.024	0.018
Ni	2.09	2.02	2.03

Manganese and phosphorus are distributed in the same direction as carbon, but not to as wide an extent. Silicon and nickel are substantially uniform, the analytical results being within the limit of error, but even in these cases the dendritic mass seems to have a slight preponderance. Nickel, it should be remarked, diffuses in molten metal with known tardiness, so that it is possible that the heat analysis—made from a 30-kg. ingot taken from the molten stream at about the middle of the tap—may not correspond exactly to the mean concentration of nickel in the ingot.

CAUSE OF INTENSE SEGREGATION

These data seem to me to indicate clearly the cause of the demonstrated segregation. It is quite significant that the differences in concentration between the den-

FIG. 5. MICROSTRUCTURE OF GRANULAR MASS

drific and the granular masses are greatest for those very elements with the greatest difference in composition between the solid and liquid phase at given temperatures during solidification.

A glance at the binary equilibrium diagrams between iron and the usual alloying elements establishes this point. Howe's diagram for carbon (Fig. 6) and Konstantinow's for phosphorus show a very considerable spread between liquidus AB and solidus AE. A vertical ordinate in the solid-solution range would have a quite long section between intercepts with AB and AE—which corresponds to the fact that a wide temperature range is traversed between incipient and completed solidification. In addition to this, a horizontal abscissa between 1,500 deg. C. and eutectic temperature would also have a comparatively long portion between intersections, denoting a wide difference in concentration between solid

FIG. 6. IRON: CARBON EQUILIBRIUM DIAGRAM ACCORDING TO HOWE¹

solution and liquid phases in contact and equilibrium at that degree. Segregation of manganese is much less, and the iron: manganese equilibrium diagram shows a smaller spread between liquidus and solidus (Fig. 8), while those alloys which have a yet narrower solidification range—iron: silicon shown in Fig. 9 and iron: nickel in Fig. 10—produce a negligible difference in the analyses.

Such facts are clear indications that the real cause of the internal discontinuity is inherent in the mechanism of separation of solid solutions from the melt.

In the particular case under discussion, the fact that the transition from metal of one composition to that notably lower in carbon and manganese occurred

¹"Metallography of Steel and Cast Iron," p. 130.

in an interval of a few millimeters certainly suggests that two crystalline masses must have formed and developed around two different nuclei at different times or rates, and their growth was only arrested by coming into contact with each other, which surface of contact is well developed by the line *LD* in Fig. 3. Considering the size of the phenocrysts, it is evident that but few abnormal or parasitic germs of primary crystallization must have been generated in the interior of the fused metal. Proceeding from these nuclei, large crystalline masses grew into being, whose chemical composition

FIG. 7. IRON : PHOSPHOROUS EQUILIBRIUM DIAGRAM ACCORDING TO KONSTANTINOW¹

varies, center to surface, in an analogous manner to that ordinarily found from the periphery to the axis of an ingot, or from the base toward the head, when crystallization is initiated at the sides and bottom. It seems clear that if two parasitic nuclei appear near each other at different times, or even if two simultaneous germs received accretion at notably different rates owing to a pronounced localized undercooling in the neighborhood of one of them, the ultimate surfaces of contact will separate various stages in the development of the phenocrysts themselves, and therefore different stages in the process of segregation with its attendant difference in chemical composition.

FIG. 8. IRON : MANGANESE EQUILIBRIUM DIAGRAM AT SOLIDIFICATION TEMPERATURES, ACCORDING TO LEVIN AND TAMMANN²

crysts themselves, and therefore different stages in the process of segregation with its attendant difference in chemical composition.

If it be granted that in this particular case the

FIG. 9. IRON : SILICON EQUILIBRIUM DIAGRAM ACCORDING TO GUERTLER AND TAMMANN³

appearance of parasitic nuclei is responsible for a structural difference in no way connected with the geometric symmetry of the ingot, it follows from the well-known mechanism of solidification that such centers of crystallization will superpose an additional segregation effect upon that due to the ordinary columnar freezing of the main mass. In fact it may well happen that random nuclei may spasmodically appear well within the fused interiors of the mass, in a molten region which has already been enriched in alloying elements by the previous separation of purer solid solution at the surfaces. Then the difference between the analyses of the central regions of several phenocrysts corresponding to various nuclei can be comparatively large, even

FIG. 10. IRON : NICKEL EQUILIBRIUM DIAGRAM ACCORDING TO OSMOND⁴

greater than the usual differences in concentration, edge to center, of an individual austenite crystal. This last conclusion seems to be verified by the analyses given above. While a minute chemical survey was not made, the macroscopic and microscopic examination amply demonstrates an extensive segregation *before* the formation of parasitic nuclei, a segregation much greater than is apparent within these phenocrysts themselves.

Cursory examination suggests that the contact surface *LH* has been impregnated with impurities. For instance, metal at and near the joint is attacked by

FIGS. 11 AND 12. NON-METALLIC INCLUSIONS AND DISCONTINUOUS STRUCTURE AT INTERCRYSTALLINE REGIONS

sulphuric acid with far greater speed than the body of the grains, etching the latter, but digging deep pits along the former. Microscopic examination of a polished surface confirms the impression, Figs. 11 and 12, showing the character of the non-metallic inclusions located there. Abundant foreign material agglomerated into masses of comparatively large dimension can be seen, much larger than those very small particles of "emulsified slag" which could occasionally be detected within the crystals themselves.

An analogous accumulation of slag and a similar agglomeration into masses notably greater than those found in other parts of the metal are frequently seen in the metal forming the walls of the pipe in steel ingots cooled very slowly; more especially in the proximity of the lower apex of this cone-like cavity. There seems no question that the metal forming the walls of the cone's apex is the last portion of the steel to solidify (at that region of the ingot, at least), and the commonly observed enrichment in insoluble impurities is habitually explained by the assumption that the slag particles, originally distributed in suspension in a substantially uniform manner throughout the melt, are gradually expelled and accumulated in the residual mother liquor, remaining fluid until the end. In other words, the mechanism of slag accumulation is intimately connected with the process responsible for the increase in concentration of elements actually in true solution in the fused steel, and which solidify in primary solid solutions in iron of a concentration less than that which exists in the liquid phase with which they are in equilibrium.

Whereas the separation of mixed crystals has been studied in detail, and there seems to be substantial agreement as to its modus operandi, certainly so much cannot be said as to the extrusion of suspended slag. Still, the explanation just advanced is in conformity with various researches to be published later. But accepting it as a fact that, in cooling, slag particles are accumulated in some manner or other in that part of the ingot last to solidify, it would seem justifiable to call upon a similar train of events to explain the presence of slag particles at the crystalline boundary *LII*, and to consider the cementing metal as the solidified last residue of liquid steel rich in impurities and slag, a mother liquor filling the voids between crystalline intersections.

CRACKS UNRELATED TO PIPING

It should be evident for three main reasons that the surface of weakness we are examining is not caused by the shrinkage pipe; first, because the fracture in question was but 800 mm. from the base of a 5-meter ingot; second, because the core cut from the ingot was

sound and free from discoverable discontinuities for three meters beyond the fracture *CDE*, at which point appeared the bottom of the pipe; and third, the surface of weakness under examination traversed the ingot for more than half of its thickness, maintaining its characteristics for that distance without change.

But even if the pipe is related to similar defects, it would hardly alter the conclusions already reached relative to the influence of parasitic nuclei upon sound metal. Such germs evidently cannot form except in liquid metal occupying a core of indefinite size, walled by austenite crystals previously separated from the melt. They can appear simultaneously or in succession, but for maximum segregation it is highly probable that one center of crystallization sprang into existence considerably later than its neighbors, in some region where by reason of eddy currents, gas bubbles or non-uniform radiation the temperature was markedly different from the average of its surroundings. Once germinated, subsequent growth by natural crystalline accretion will account for all the abnormalities noted in the study of this ingot, especially if the phenomenon of undercooling or surfusion occurred before crystallization began, in which case the speed of growth is very largely increased.

DANGERS OF SUCH VARIATIONS IN COMPOSITION

From a technical point of view, the consequences of large heterogeneities are essentially of two kinds.

First, notable differences in the carbon content of contiguous masses in the steel can render difficult or impossible the production of desired and expected results from a heat treatment predetermined for metal of the same average analysis and condition. In particular cases it is clearly impossible to follow general rules, and the best approximate thermal treatment must be

FIG. 13. Curves of expansion and contraction of adjacent crystals possessing considerable difference in composition

studied individually. Practically, it is often the failure of steel parts to respond uniformly in the heat-treatment department which gives the first indication of large-scale segregation.

Second, as we have already seen in this study, the joint between metallic masses of different composition is ordinarily a surface of weakness which develops dangerous flaws. This weak bond, fracturing under mechanical work, is due primarily to the collection of impurities, and more especially slag inclusions, which originally were substantially uniformly distributed in the melt. Another very important cause of flaws lies in the differential thermal expansion of the adjacent phenocrysts, which effect is especially marked in the transformation range, where there evidently occurs what may be called a mutual "phase displacement."

As a concrete example of the last cause, I have prepared in Fig. 13 the expansion and contraction curves characteristic of the two steels whose composition corresponds to that of the two parts adjacent to surface *LD* (Fig. 3). Upper curve 1 is expansion versus temperature for the low-carbon granular steel, while upper

*Obtained optically by the method described by Le Chatelier and Broniewski, *Revue de Metallurgie*, March, 1913, p. 133.

curve 2 is the same curve for the higher-carbon, dendritic metal. Lower curves 1 and 2 are the contraction curves respectively.

From these graphs it is at once evident that the change in volume with temperature on either heating or cooling is practically the same except when passing through the critical range. It follows that when the metal is cooling from 710 to 680 deg. C., one part of the metallic mass may be considerably shrunken while the other has suffered only a small change in volume. A corresponding effect, but to a much less extent, will occur when the procedure is reversed by heating.

PREVENTION OF LARGE-SCALE SEGREGATION

It would be interesting to note the steps which have been taken at various steel works to prevent wholesale segregation by formation of parasitic nuclei, but the matter can only briefly be mentioned here. The writer is acquainted with very satisfactory methods in use at Italian plants largely occupied with munitions which have been maintained secret for several years, and which he is at liberty to mention only in general terms. It must suffice to say the following:

In the first place, one may select steels of such a composition that in them the greatest number of crystallization nuclei appear immediately below the formation of the first primary austenite crystals. Composition has a great deal to do with the existence of parasitic nuclei. Witness the fact that in a 20-point carbon steel containing 2 per cent nickel, manganese must be held lower than 0.4 per cent. If manganese by chance runs higher than this figure, the fact is immediately apparent in troubles with internal cracking at interfaces between crystals of widely differing composition. An important Russian plant utilizes the principle of cooling the steel through the mushy stage with extreme rapidity, while Americans habitually cast their metal at a temperature very close to the liquidus. I am informed that the Russian practice consists in casting in slightly conical molds; then as soon as the metal is walled in sufficiently to stand up, the mold is raised slowly, the hot metal being simultaneously drenched with pressure water from appropriate nozzles as fast as it is exposed. I also understand that a process of mechanically disturbed crystallization has been studied and applied successfully in at least one American plant making high-grade forgings. Such a system of stirring and jarring would work on the same principle utilized in salt technology, where crystallizing pans are equipped with stirrers when a uniform grain size is desired; quiescent cooling will cause extended supersaturation and the formation of crystals of widely differing mass.

NECESSITY TO RECORD OBSERVATIONS

It would certainly be of greatest technical and commercial interest to collect and co-ordinate a sufficient quantity of experimental data that the crystallization criteria for various types of steels could be established with a fair degree of accuracy, following the general theory of Tammann. Data on the linear velocity of crystallization and on the number and distribution of crystallization nuclei appearing when the metal cools with differing speeds would be the most important. The relation between the width of the mushy stage and the generation of crystalline centers should also be studied. Such a systematic research would undoubtedly allow one to synthesize a procedure capable of pre-

venting such segregation as that just illustrated; it would, however, present such great experimental difficulties as to render its successful conclusion very doubtful. It is therefore opportune to insist upon the importance of collecting the greatest amount of precise and complete data upon such defects as occur in regular works practice. From such a mass of evidence it may be quite possible to deduce the causes by an analysis of the concomitant circumstances, and so prescribe the necessary remedy, and even draw general conclusions of wide application. Certainly there are not lacking examples of complex technical processes—such as the chemistry of the open-hearth—which would be most difficult to elucidate by proceeding with synthetic studies in order to reconstruct the entire process on the basis of systematic data on the underlying elementary principles, yet it has been possible to reach very useful conclusions by following the opposite path, that is, by an analysis of the problem itself as it is in operation commercially.

Wood-Distillation Industry of Canada

The production from wood-distillation plants in Canada in 1918 (the latest year for which statistics are to be had) was valued at \$7,634,122, this total including the item of \$398,905 for repairs to machinery and plant made by employees.

There are thirteen plants, of which eight were located in Ontario and five in Quebec, with one refinery in each province. The amount of capital invested was \$3,612,573, of which Ontario's portion was \$2,321,881 and Quebec's \$1,290,692.

The amount paid in salaries and wages to 675 male and two female employees was \$731,435.

The charges for fuel of all sorts used during the year amounted to \$839,966, of which \$67,954 worth was of Canadian origin and \$772,012 of foreign origin. Miscellaneous expenses totaled \$365,789, and included such items as rent, power, insurance, taxes, traveling expenses and ordinary repairs to buildings and plant.

The quantity and cost of all materials delivered at the works during the year were:

Materials Used	Quantity	Cost Value at Works
Hardwoods, cords	128,097	\$1,321,893
Lime, bushels	140,420	57,423
Crude wood alcohol for further manufacturing, gal.	1,081,837	1,071,227
Acetate of lime for further manufacturing, lb.	20,868,427	829,675
Caustic soda, lb.	186,900	7,709
Sulphuric acid, lb.	1,050,240	11,527
Soda ash, lb.	234,191	13,637
Other miscellaneous materials, lb. ..	445,986	6,640
Total		\$3,319,731

The quantity and value of the various products of the industry at the point of production are given in the following table:

Products	Quantity	Selling Value at Works
Wood alcohol: Crude (sold as such), gal.	875,024	\$981,535
Refined (sold as such), gal.	1,070,928	1,531,356
Acetate of lime, lb.	25,998,139	1,017,465
Acetic acid, lb.	1,772,233	170,173
Acetate of soda, lb.	295,572	51,389
Acetone, lb.	3,458,810	909,570
Formaldehyde, lb.	1,154,902	159,268
Ketone oils, lb.	792,864	211,440
Acetic anhydride, lb.	44,981	60,515
Methyl acetate, lb.	132,121	29,350
Charcoal, bushels	6,472,925	1,575,701
All miscellaneous products		537,460
Repairs to machinery and plant by employees		398,905
Total		\$7,634,122

Properties and Constitution of Glues and Gelatines—IV

The Physical and Chemical Significance of "Craze" — Moisture Fluctuations — Relation of "Craze" to Nitrogenous Constitution—Studying Chemical Constitution by Determination of the Groups Characteristic of the Amino Acids—Purified Protein Analysis*

By ROBERT H. BOGUE, Ph.D.

SOME of the low-grade bone glues, after thoroughly drying out by exposure to the air for some time, craze badly. It is believed that this property of crazing not only detracts from the appearance of the glues and lowers their selling value, but also that a crazed product is of less strength in service than a glue of a similar grade which will remain firm. It seemed that an investigation of this peculiar property of crazing might reveal relations which would be of value both from the scientific point of view and from the standpoint of the manufacturer. This study was accordingly undertaken.

MOISTURE FLUCTUATIONS

It was noticed that in several instances low-grade glues would remain firm in the barrels, while those same glues in storage in the cabinet of samples would, after a short time, become badly crazed. This suggested that the water which such a glue would retain, after it had reached equilibrium with the air, was very likely a determining factor. To test this point several glues which were crazed in the cabinet but firm in the barrels were examined for water content. The results showed clearly that the cabinet samples had lost much more water than the firm samples in the barrels. The firm samples were then allowed to dry out in the air of the laboratory, and the water content determined at the time when crazing became apparent. This "critical moisture content" was found to be nearly, or slightly above, that found in the cabinet samples.

TABLE XXXVII. RELATION OF WATER CONTENT TO CRAZING

No.	Firm from Barrels	Crazed from Cabinet	Critical Moist Content
1	16.06	11.04	11.36
2	14.98	11.36	11.84
3	16.98	11.24	11.44
4	16.98	10.88	11.52
5	16.10	10.84	11.24
6	15.80	11.14	11.54

It is apparent, therefore, that the water content of a glue that has reached equilibrium with the air is an important factor influencing the crazing of glues, for it seems that if the water content falls below a certain minimum amount, the low-grade glue will craze.

PROXIMATE ANALYSIS

It was known that of several glues of uniform grade, some would craze and others would not, even when equilibrium with the air had been reached. In order to ascertain if this fact were caused by differences in the proximate constituents of the glues, a number of glues of low grade, some of which were crazed and others not, were analyzed for water, ash, organic matter and nitrogen.

An examination of the results does not reveal any marked or consistent relation between the proximate constitution and craze

TABLE XXXVIII. RELATION BETWEEN PROXIMATE CONSTITUTION AND CRAZE

	No.	Grade	Viscosity	Water	Ash	Organic Matter	Nitrogen
Crazed glues	1	B7	43	12.74	3.74	83.52	14.58
	3	B8	44	13.62	3.22	83.16	14.64

	12	B8	42	11.86	3.29	84.65	14.10
	14	B8	43	11.48	3.07	85.45	14.35
Average crazed		B8	43	11.99	3.35	84.77	14.56
Average firm		B8	43	11.91	3.75	84.44	14.39

RELATION OF CRAZE TO NITROGENOUS CONSTITUTION

Having found no relation between the proximate constitution of glue and the development of craze, the nitrogenous constituents, protein, proteose, peptone and amino acids were next determined in the same series, by the method described in a previous paper⁶⁰. The data obtained are given in Table XXXIX.

TABLE XXXIX. RELATION OF CRAZE TO NITROGENOUS CONSTITUTION

	No.	Grade	Viscosity	Protein N	Proteose N	Peptone N	Amino Acid N
Crazed glues	1	B7	43	47.4	41.0	9.8	1.8
	3	B8	44	44.7	42.5	11.2	1.6
	5	B9	46	52.6	35.8	10.8	0.8
	7	B8	42	23.6	53.6	19.3	3.5
	9	B9	42	30.5	53.0	13.9	2.6
	11	B8	42	34.0	51.7	12.1	2.2
	13	B9	43	39.3	45.5	12.8	2.4
Firm glues	2	B7	43	48.9	39.3	10.4	1.4
	4	B8	44	44.0	43.2	11.0	1.8
	6	B9	45	51.4	41.5	6.1	1.0
	8	B8	43	33.6	51.9	11.8	2.7
	10	B9	42	32.6	48.1	15.7	3.5
	12	B8	42	35.4	51.1	10.9	2.3
	14	B8	43	50.1	36.7	11.1	2.1
Average crazed		B9	43	38.9	46.2	12.8	2.1
Average firm		B8	43	42.3	44.6	11.0	2.1

It will be seen from the data obtained that the firm samples are higher in protein and lower in proteose and peptone than the crazed samples. The amino acid nitrogen is about the same in the two sets. The grades and viscosities of the two sets are identical, as determined by the usual methods.

It was previously concluded⁶¹ that the jell strength was determined by the ratio between the protein and its products of hydrolysis, the corollary of which would be that glues of the same jell strength would contain the

*For Parts I, II and III see CHIMM. & MET. ENG., vol. 23, Nos. 1, 2 and 3, July 7, 14 and 21, 1920, pp. 5, 61 and 105.

⁶⁰See Part III.

⁶¹See p. 107.

same amounts of protein. With the crazed glues, however, we find that glues of the same "grade" do not contain equal amounts of protein. The reason for this seeming contradiction lies in the limitations of the methods commonly employed for testing jell strength and viscosity. For example, grade B, will produce a very weak jelly in 1 to 5 solution; grade B, will not jell at that concentration. There may be a very wide variation in composition between those two grades. Again, the viscosity of most of these glues is 42 and 43. By the same instrument water has a viscosity of 42. Therefore, at such low values the composition may vary greatly before it becomes measurable by the apparatus usually employed.

The fundamental statement²², therefore, that jell strength is proportional to the protein content is not contradicted. The crazed glues are actually a lower grade of glue, their jell strength is actually lower, even though it is not measurable by the usual tests, and they consequently contain a smaller amount of their nitrogen in the protein condition.

On correlating these observations with the previously determined fact that glues do not craze until they have been reduced to a certain minimum water content, it seems that the ability of a glue to retain water above a certain minimum amount depends upon its protein content. Crazing is therefore due to an exceptionally great hydrolysis of the protein molecule and the consequent inability of the resulting mixture to retain water above that minimum content below which crazing may occur.

ON CHEMICAL CONSTITUTION BY DETERMINATION OF THE GROUPS CHARACTERISTIC OF THE AMINO ACIDS

The writer has shown²³ that the highest grade first run glues contain about 90 per cent of their nitrogen in the form of protein, while the lower grades, which are the last runs, may show only about 50 per cent of their nitrogen as protein. If the difference lay solely in the degree of hydrolysis of the same protein, it would of course follow that the ultimate nitrogenous constitution of the two would be identical. If, as seemed probable, the later boilings not only contain a larger proportion of their original protein nitrogen in a more or less hydrolyzed state, but have also obtained some of their nitrogen from a source differing from that of the original protein, then the ultimate nitrogenous constitution would probably not be the same in the two glues. The solution of this phase of the problem should be obtained by a nitrogenous analysis of the original glues.

It has been shown by Fischer²⁴ and many others that the protein molecule is made up of a number of amino acids, about twenty being known, and that these are linked together in the protein molecule by anhydride combinations between the amino group of one amino acid and the carboxyl group of another. Moreover, it appears that the characteristic physical and chemical nature of the different proteins is determined by the type and percentage of the several amino acids present in the molecule. It is, therefore, apparent that in order to make a comparison of the chemical constitution of the protein it is necessary to split them into their constituent amino acids. There is no method known by which the exact manner of combination may be found.

Even the very sensitive "anaphylaxis reaction is not invariably specific, as has been shown by Wells and Osburn²⁵. Neither is there any method known by which each and every amino acid in the protein decomposition product may be determined quantitatively. They may all be isolated and identified by the esterification method of Fischer²⁶, but besides being very long and exacting the results are in no degree quantitative. The most careful work leaves from a third to a half of the protein molecule still unaccounted for. Hausmann²⁷ devised a method for the separation of the several groups of amino acids, and this principle has been extended and modified by Van Slyke²⁸. By the utilization of this method one is able to separate the amino acids into eight groups, and this separation is quantitative.

THE METHOD

The protein is first subjected to prolonged hydrolysis with hydrochloric acid, after which the ammonia is removed by vacuum distillation, and the melanin filtered off and determined from the Kjeldahl value. The "bases" arginine, histidine, lysine and cystine are then precipitated with phosphotungstic acid. These "bases" after separation from the filtrate are redissolved and determined by their marked chemical differences. Cystine is determined directly by its sulphur content, and arginine by decomposition of the molecule with strong potassium hydroxide. The molecule of arginine breaks up into a molecule each of urea and ornithine. The urea is decomposed into ammonia. None of the other bases are attacked. By determination of the total nitrogen and the amino nitrogen, the non-amino nitrogen is obtained. This is derived from the arginine, which contains three-fourths of its nitrogen in a form which does not react with nitrous acid, and from the histidine, which contains two-thirds of its nitrogen in non-amino form. The histidine nitrogen is, therefore, calculated by subtracting three-fourths of the arginine nitrogen from the total non-amino nitrogen, and multiplying the difference by three-halves. This is easily seen from the following equations, letting A = arginine nitrogen, H = histidine nitrogen, and N = total non-amino nitrogen:

$$\begin{aligned} 3A + 3H &= N \\ H &= \frac{N - 3A}{3} \quad \frac{2}{3}(N - 3A) = 1.5N - 1.125A \end{aligned}$$

The lysine nitrogen is obtained by subtracting the sum of the nitrogen of the other three bases from the total nitrogen of the bases.

In the filtrate from the bases the amino acids are divided into two groups by a determination of the amino nitrogen and the total nitrogen; i.e., the acids containing only primary amino nitrogen; and those containing nitrogen in pyrrolidine or indole rings.

The eight groups, therefore, which are determined by the Van Slyke method are briefly as follows:

Ammonia, or amide nitrogen, considered to be derived from -CONH₂ or CONHOC- groups linked to the carboxyl groups of the dicarboxylic acids in the protein molecule (glutamic and aspartic acids).

Melanin, or humin nitrogen, from the dark colored pigment and slight amount of insoluble matter always formed in the hydrolytic products of acid hydrolysis of

proteins. It has been shown by Gortner and Blish⁶⁶ that "in all probability the humin nitrogen of protein hydrolysis has its origin in the tryptophane nucleus." They have found that when tryptophane was boiled with mineral acids in pure solution no humin was formed, but when tryptophane was added to a protein, or when carbohydrates were present, an abundance of humin was formed. They recovered up to 90 per cent of the tryptophane nitrogen in the humin fraction.

FIG. 18. VARIATION IN THE AMINO ACID CONSTITUENTS ON PASSING FROM THE HIGHEST TO THE LOWEST GRADE GLUES

all of the mono-amino acids except proline and oxyproline.

Non-amino nitrogen of the filtrate, which corresponds to proline and oxyproline, and some of the tryptophane. (Of the tryptophane which is not retained in the humin fraction one-half will appear as amino and one-half as non-amino nitrogen of the filtrate. In exceptional cases a portion of the tryptophane may also be precipitated by the phosphotungstic acid, and be calculated as histidine and lysine⁶⁷.)

EXPERIMENTAL

Hide and Bone Glues. This analysis was therefore undertaken, employing for the purpose all of the standard grade hide and bone glues. The results are expressed in Tables XL and XLI. Fig. 18 shows the variation between the highest and lowest grades of hide glue and of bone glue. Fig. 19 shows the variation between the average of the hide and of the bone glues.

The results may be summarized as follows:

The ammonia nitrogen increases as the grade decreases, and is decidedly higher in the bone glues than in the hide glues.

	H ₁	H ₂	H ₃	H ₄	H ₅	H ₆	Average
Ammonia N.....	1.63	1.89	3.20	2.15	2.44	2.49	2.90

Amino N in filtrate.....	47.5	56.3
Non-Amino N in filtrate.....	3.1	14.9
Total regained.....	98.85	99.02

The melanin nitrogen is nearly constant within each series, but it is higher in the bone than in the hide glues.

Cystine appears to be practically absent in all cases, traces only being found in two instances.

Arginine varies slightly from glue to glue, but shows

FIG. 19. VARIATION BETWEEN THE AVERAGES OF THE HIDE AND BONE GLUES

no consistent variation with grade. It is somewhat higher in the hide series.

Histidine varies irregularly, but is higher in the hide series except in the case of the pressure tankage from bones where it shows a maximum.

⁶⁶J. Am. Chem. Soc., vol. 37 (1915) pp. 1630-1636; and Science, vol. 48 (1919), p. 122.

⁶⁷Van Slyke, J. Biol. Chem., vol. 10 (1911), p. 40.

⁷¹The glues are arranged in order of decreasing jelly strength.

⁷²Van Slyke, loc. cit.

Lysine is fairly uniform in both series, increasing slightly, however, in the lower grades of bone glue.

Amino nitrogen of the filtrate is irregular in variation, but shows a tendency to decrease as the grade, especially in bone glues.

Non-amino nitrogen of the filtrate also shows a tendency to decrease as the grade, and is somewhat lower in the bone series.

CONCLUSIONS

Three conclusions may be drawn from the above summary of results:

There seems to be a sufficiently consistent variation from grade to grade in the case of a few constituents to justify the following conclusion: As boiling of the glue stock progresses, and under the influence of higher temperatures, some proteins of the stock will be hydrolyzed and brought into solution which were not at all or only slightly attacked during the first boilings. The first reaction is unquestionably the hydration of collagen to gelatin, but by the more drastic and continued extrac-

glue, thereby largely eliminating the high melanin fraction and raising certain other fractions accordingly, it will be seen that the divergence from glues is not striking. However, such differences as exist are in harmony with the variations that actually occur in passing from a high- to a low-grade glue, or from a hide to a bone glue. This does not prove that keratin is present in low-grade glues, but it suggests the possibility, and at least is not opposed to the hypothesis that some foreign proteins such as keratin have been hydrolyzed.

There is a sufficiently marked variation between hide glues and bone glues to justify the conclusion that the proteins from which they are derived are different, or at least that the ratio of the constituent proteins is different. This is shown most decisively in the ammonia fraction, it being much higher in every instance in the bone than in the hide glues. This indicates a higher content of the dicarboxylic acids, glutamic and aspartic.

The inconsistencies among the results may reasonably be laid to differences existing in original stock from which the several glues were made.

PURIFIED PROTEIN ANALYSIS

In order to determine to what extent the difference between the hide and the bone glues was due to their protein content, as distinguished from the products of protein hydrolysis, a representative high-grade hide glue (H_1) and a low-grade bone glue (B_1) were each subjected to alcoholic precipitation by slowly pouring the dilute glue solution into cold 95 per cent alcohol, redissolving in warm water and reprecipitating four times. These purified proteins were then subjected to the same determinations as the original glues. The results are shown in Table XLIII, and the variations are expressed graphically in Fig. 20.

TABLE XLIII. PURIFIED PROTEIN, FISH GLUE AND ISINGLASS ANALYSIS

	H_1 Protein	B_1 Protein	Fish Glue	Isinglass
Ammonia N...	1.33	3.57	5.15	3.98

FIG. 20. VARIATION IN THE AMINO ACID CONSTITUENTS BETWEEN THE HIGHEST HIDE GLUE PROTEIN (H_1) AND THE PROTEIN OF THE LOWEST BONE GLUE (B_1). WHOLE GLUES SHOWN ALSO

tion such substances as chondridin, keratin and mucin may be brought into solution. Whether or not the analyses as performed would show this point to advantage must depend upon the constitution and amount of these hydrolyzed substances so produced. If the constitution of the hydrolyzed chondridin, keratin or mucin were markedly different from that of gelatin, the presence of the former would be easily detected even in small amounts, but if the differences in constitution were but slight, their presence would be detected with difficulty by this method, even if present in large amounts. The only comparable analysis which has been made of any of these substances is one of dog hair, which is largely keratin, reported by Van Slyke". This is given in Table XLII. When it is remembered that only the soluble portion could by any chance get into

The differences between the constitution of these two purified proteins are still large, especially in ammonia, arginine, histidine, and amino nitrogen of the filtrate. However, they are not as great as existed between the original whole glues, and variations which previously existed, as in melanin, lysine and non-amino nitrogen of the filtrate, have disappeared.

HIDE AND BONE GLUE PROTEINS

This seems to show that:

The proteins of the hide and bone glues are fundamentally different in some respects, and are unquestionably derived from protein complexes which are different, or in which the ratio of the constituent proteins is dissimilar.

This is corroborated further by the great difference in physical properties of the two purified proteins. That from hide glue is white, and forms very tough leathery masses which are not sticky, while the bone protein, although white at the moment of precipitation, very rapidly becomes brownish, and is a sticky, soft, gummy

mass. Repeated precipitations fail to alter these properties.

The constitution of the whole glues used varies more than that of the isolated proteins, which shows that even more of the "foreign substances" of bone glues, which reduce their value, are present in the proteose and peptone fractions than in the protein fraction.

ISINGLASS AND FISH GLUE

It has been claimed by some investigators that the soluble portion of Russian Sturgeon-sound Isinglass was pure gelatin. For the purpose of comparison, it was decided to make a "Van Slyke analysis" of this substance. The results are given in Table XLIII. It will be seen that the arginine nitrogen is higher and the lysine nitrogen lower than in any other analysis. The ammonia nitrogen is high, and the non-amino nitrogen of the filtrate is low, but in general the figures correspond somewhat more closely to Van Slyke's analysis of gelatine¹, shown in Table XLII, than any other glue. It is also apparent that in most of the groups the high-grade hide glues more nearly correspond in value to the analysis of isinglass than the bone glues.

To obtain still further comparative data a fish glue was analyzed. The results are given in Table XLIII. This glue shows higher ammonia, melanin and amino nitrogen of the filtrate, and lower non-amino nitrogen of the filtrate than any other glue, but more nearly corresponds to the low-grade bone glues than to the hide series. Only in its high amino nitrogen of the filtrate does it resemble the latter. The very low non-amino nitrogen of the filtrate in the case of both of the fish products indicates a fundamental distinction from animal glues.

The variations of isinglass and fish glue from the highest grade animal glue protein (H_1) is shown in Fig. 21. The curve for the average of all animal glues is also included. It would seem from this that there is much difference between the constitution of isinglass and the pure animal protein, and if either one of these may be assumed to consist of pure gelatin, the other must of necessity contain considerable impurity.

SUMMARY

The conclusions detailed in this section may be briefly recapitulated as follows:

Hide and bone glues vary slightly in their chemical constitution on passing from grade to grade. This is interpreted to signify that as the boiling of a glue progresses some "foreign substances" as chondridin, keratin, mucin, etc., become hydrolyzed and enter the solution. These have no value in glue, and by adulteration lower the value of the product.

Hide and bone glues differ from each other in their chemical constitution. This is taken to signify that the protein complexes from which the glues are derived are different in the two cases, or that the ratio of the several constituents is different.

Glues of different stock within both hide and bone series show a difference in constitution, which is attributed to variations in the protein complexes of the several stocks.

The differences between hide and bone glues are found in the protein fraction to a lesser extent, and in the proteose-peptone fraction to a greater extent than obtained in the whole glues.

If the purified protein from the highest grade animal glues may be considered as pure gelatin, then it follows that isinglass is not a pure gelatin, or if the assumption be made that isinglass consists only of gelatin, then the purified animal glue protein contains impurities.

FIG. 21. THE VARIATION, FROM THE HIGHEST ANIMAL GLUE PROTEIN, OF AVERAGE ANIMAL GLUES, ISINGLASS AND FISH GLUES

The lower the grade of a glue, the further is it removed in constitution from that of the purified protein, and, if, this protein be assumed to consist only of gelatin, then the gelatin content of glues diminishes with the grade, and the substance from which the hydrolytic products are obtained consists of gelatin in decreasing amounts, as the grade decreases.

Fish glue corresponds more closely in its composition to low-grade bone glue than to any other.

Fish glue and isinglass show a fundamental difference from animal glues in their low "non-amino nitrogen of the filtrate" (proline, oxyproline, and tryptophane).

(Part V will be published in the next issue.)

Progress in Optical Glass Manufacture

Another triumph of American ingenuity is the manufacture of optical glass. Prior to the war practically all this material was produced abroad, but the cessation of imports and the great need of lenses for field glasses, telescopes, and other optical devices used in warfare, necessitated immediate investigation as to the possibility of optical glass manufacture in this country. Experiments were carried on and the process so successfully developed that not only the smaller lenses for field glasses but also the larger types which are used in telescopes were manufactured. Lenses up to 20 in. in diameter are now made and larger ones contemplated.

Great difficulty was experienced in the annealing process necessary to remove internal strains which cause the lenses to crack on cooling. To overcome this, however, a new electric furnace has been designed which gives a much closer control of temperature during the annealing, and one company soon expects to have all sizes of lenses up to 20 in. and over on the market.

The Evaporator Experiment Station at the University of Michigan*

An Account of the Institution of the Evaporator Laboratory — Description of the Vertical, Horizontal and Semi-Film Evaporators and Miscellaneous Equipment—
Program of Investigations Proposed

By W. L. BADGER AND P. W. SHEPARD

THE subject of co-operation between industrial concerns and universities has been discussed so frequently that this general question will not be taken up here. It is proposed, however, to describe what is believed to be a very noteworthy case of such co-operation.

During the summer of 1917 the Swenson Evaporator Co., of Chicago, Ill., was considering the establishment of an evaporator experiment station to study both general theoretical questions and detailed concrete problems regarding evaporator design. The possibility and desirability of co-operation in this work with some university became apparent early in the development of the idea; and the matter was taken up with the Board of Regents of the University of Michigan. After a careful and extended discussion by both parties an agreement was reached substantially as follows:

The university furnished a suitable building, light, water, steam and power, and assumed responsibility of providing equipment for making all necessary measurements involved; this consisting of such articles as weighing devices, thermometers, gages, manometers, recording instruments, volumetric measuring devices, etc. The Swenson Evaporator Co. bore the entire expense of designing, building and erecting the machinery; and as soon as erected, its title passed to the University of Michigan. The whole station, then, is the property of the university and is available for instruction, demonstration and research. In return for this investment the university granted to the Swenson Evaporator Co. the right to carry out certain detailed investigations of its own, the right to maintain in this laboratory its own employees and the right to retain as its own property the results of certain specific classes of detailed investigation. It was expressly provided, however, that in case any facts of general scientific importance were developed, they were to become public property even though they were developed by the company's employees and at the company's expense.

WORK DELAYED BY WAR

The design of the apparatus was immediately started, but its manufacture and delivery were greatly delayed due to conditions arising out of the war. Actual equipping of the laboratory did not begin till March, 1918. The principal equipment was added as rapidly as possible, but the final layout was not ready till August, 1919. Due to lack of graduate chemical engineering students during the war, the work so far has been largely carried out by the company's employees and at the company's expense. The two papers accompanying this description fall in this class. Acknowledgment is

made to E. M. Baker, instructor in chemical engineering in the University of Michigan, who has taken an active part in the development of the laboratory and the prosecution of the research.

The principle adopted in planning the equipment was to make all units large enough to minimize personal errors and errors due to small-scale work. The station was to furnish data for actual engineering design—not only for evaporators but for entire plants and complete processes. Consequently all units installed were of commercial size, and results obtained in them are transferable quantitatively to full-scale commercial operation. Much thought was given to all possible problems, both general and specific, which might arise. Provisions were accordingly made for changing the set-up and connections, taking temperature and pressure measurements, and in general anticipating the requirements of the most varied and intricate work which could be expected. Attention was given to making it possible to secure ample data for every step of an experiment. Every problem, both general and specific, which the station takes up, is treated quantitatively. This is not only for the sake of collecting a general fund of information regarding the behavior of evaporators but also that all possible problems which might arise in development of the process experimented on might be forestalled.

EQUIPMENT INSTALLED

Since the primary purpose was to study evaporator design, one representative of each of the three common types of evaporators was provided. Accordingly the station has a vertical tube, a horizontal tube and a film type evaporator following the standard designs of the Swenson Evaporator Co. for each type. To handle problems where crystals are deposited there is a salt filter which may be used on either the horizontal or vertical tube evaporator. To make possible the solution of the widest variety of problems, the heating surfaces of each evaporator were made easily removable and a wide variety of methods of disposing or arranging the heating surfaces was provided. Parts forming vapor belts were made interchangeable so that the main dimensions of the machines could be altered at will. Several types of bottoms were provided and made easily removable and interchangeable.

The station also possesses a number of storage tanks, so that several materials may be on hand at one time. Capacity is provided for storing a tank car of liquid. Pumps and pipe lines make all possible combinations available. One tank is provided with an agitator for making up solutions.

Operations of interest to the chemical engineer other than evaporation have not received as much attention as evaporation, but are being added rapidly. A filter,

*Read before the American Institute of Chemical Engineers, Montreal, June 29, 1920.

FIG. 1. GENERAL VIEW OF EVAPORATOR LABORATORY

a centrifugal, a crystallizer and a steam-jacketed kettle are now installed.

The station is housed in a building which was formerly the university power house. The old boiler room contains the laboratory proper. This is 65 x 35 ft. in plan; the floor is 15 ft. below ground level, and the roof extends in part to a height of 35 ft., giving ample head room. This room still contains the university's distribution system for steam, electricity and water, though the mains are now supplied from a new power house. A bunker 60 x 20 ft. is available for storage. The room is well adapted for the purposes of the work that will be done. In the front part of the building is an office and a drafting room for the use of the station staff. A good idea of this building is given in Fig. 1.

VERTICAL TUBE EVAPORATOR

The vertical tube evaporator (Fig. 2) is of the Swenson patented basket type. This choice was made not only because the Swenson Evaporator Co. was naturally most interested in this type of evaporator (as representative of vertical tube machines), but also because it made alterations of the heating surface much simpler. The body of the evaporator is of cast iron 30 in. inside diameter, and is built in 4-ft. sections. The bottom section carries connections for feed and wash water. Condensed steam from the basket is taken out through a stuffing box in this section. Intermediate sections have no pipe connections in ordinary operations. A pad is provided along one side of all sections. This carries a number of openings tapped for 2-in. and 1-in. pipe. All ordinary connections are made through these openings, and such special piping as may become necessary is thus anticipated. The top section carries the steam connections. A 1½-in. line brings steam at about 100 lb. and a 3-in. line brings steam at about 3 lb. These unite in a "T" into a 3-in. line which passes through the top section and down the center of the evaporator to the steam basket. Some runs have been

made with the top and bottom actions only, making the evaporator 8 ft. high. Most of the work has been done with one intermediate section, making the evaporator 12 ft. high. Another intermediate section is provided so that the evaporator can be carried to a height of 16 ft. if desired. The vapors are removed from the evaporator by a 10-in. cast-iron pipe to a wet parallel current condenser, which, instead of being mounted near the top of the evaporator, as is customary, is located on the operating floor so as to be available for test.

The steam baskets provided for this evaporator are all of 18-in. O.D. and carry twenty-four 2-in. charcoal iron tubes. They have a 3-in. central steam inlet and six 1-in. connections around the outside edge of the top head for manometer connections, etc. Condensed steam is removed by a 2-in. pipe flush with the bottom head. Four baskets are at present provided with

FIG. 2. DIAGRAMMATIC SKETCH OF VERTICAL TUBE EVAPORATOR

FIG. 3. VERTICAL TUBE EVAPORATOR WITH CONE BOTTOM AND SALT FILTER

tubes respectively 30 in., 48 in., 60 in. and 84 in. long. Baskets of this diameter give an annular down-take space of 6 in. This makes a very much larger ratio of downtake area to tube cross-section than is usual, but this was done purposely. The question of the proper value for this ratio is a rather important one on which no direct evidence is available. Sheet-iron filler cylinders are provided to reduce the diameter of the machine at the level of the steam basket so that the down-take ratio can be varied and the effect of changes in the ratio may be studied. This problem has not yet been taken up. The purpose of providing baskets of different tube lengths was mainly to study the question of ratio of tube length to tube diameter. Considerable work has been done on this, but the results will not be ready to report for some time.

The evaporator is provided with three bottoms—a flat bottom, a 60-deg. cone bottom, and a special cone bottom with provision for forced recirculation by an arrangement patented by the Swenson Evaporator Co. (called the "Jumbo" bottom). A salt filter, 24 in. in diameter and 18 in. high, is mounted on a truck at such a height that it may be connected by a 3-in. gate valve to the standard hopper bottom. Set screws in the brackets of this filter make its exact adjustment a simple matter. The filter is provided with monel metal screen held between two heavy perforated plates. (See Fig. 3.)

The evaporator is set so that the bottom flange of the lower section is about 8 ft. from the ground floor. An overhead trolley is provided for handling heavy parts. The various bottoms have brackets bearing rollers. Removable tracks may be quickly bolted to the columns which support the evaporator. When it is desired to change the bottoms on the evaporator, the

tracks are put in place, the bottom which is in service is unbolted and lowered to the tracks (about 2 in.), rolled from under the machine and removed by the chain-falls. The new bottom is hoisted on the tracks, run under the machine and lifted into place by drawing up the bolts.

HORIZONTAL TUBE EVAPORATOR

The horizontal tube evaporator (see Fig. 4) is approximately 30 in. wide by 4 ft. long inside, made of ribbed rectangular cast-iron plates. The ends of the evaporator in ordinary commercial design are the tube sheets. In this evaporator, in order to make changes simple, the sides and bottom are assembled on a cast-iron frame called the front plate; and to this front plate is bolted the tube sheet. This makes it possible to change tube sheets, thereby permitting the study of such problems as varying the diameter of the tubes, varying their spacing, putting in circulation belts, etc. The tube sheets generally used take $\frac{3}{4}$ -in. O.D. tubes, on 1 $\frac{1}{2}$ -in. centers. This makes room for sixteen tubes in each horizontal row and twenty-eight in each vertical

FIG. 4. DIAGRAMMATIC SKETCH OF HORIZONTAL TUBE EVAPORATOR

row. It is not intended that all these be used at once. Generally from forty to seventy-five tubes are used. They have an effective length of 3 ft. 10 in. and a heating surface of 0.75 sq.ft. per tube. The steam chests are cast box shape and have condensate drains from the bottom of each. Several vapor belts, each 27 in. wide, are provided, and the minimum height of machine is about 5 ft. This evaporator is also provided with a 10-in. vapor pipe, and its condenser is the same as the one on the vertical. Like the vertical evaporator, it is mounted on brackets so that the bottom is entirely unobstructed. It is provided with a flat bottom and also with a hopper bottom. It is set at such a height that when it is equipped with the hopper bot-

tom the salt filter which serves the vertical evaporator will fit it also. The salt filter is mounted on a truck, which makes it easy to transfer from one evaporator to the other. The hopper bottom is provided with a

FIG. 5. DIAGRAMMATIC SKETCH OF SEMI-FILM EVAPORATOR

stuffing box so that the effect of forced circulation may be tried here also.

SEMI-FILM EVAPORATOR

This evaporator (see Fig. 5) is the third representative in the station and offers several interesting features. It is patented by the Swenson Evaporator Co.

and is known as the company's "Type K" evaporator. It is primarily a horizontal tube evaporator similar to that just described except that it is only about 15 in. wide. It carries, however, 2-in. tubes. Corresponding to the steam chests of the horizontal tube evaporator are two steam belts, one on either end, and these steam belts, instead of being closed by a cover plate as in the ordinary horizontal evaporator, are closed by secondary tube sheets. These secondary tube sheets carry 1½-in. tubes concentric with the 2-in. tubes in the primary tube sheet. These 1½-in. tubes are connected in series on the outside of the evaporator by means of special return bends.

Steam is passed into one of the steam belts and thus enters the annular spaces between the 2-in. and the 1½-in. tubes. The liquid to be evaporated is pumped into one of the return bends and circulated back and forth through all 1½-in. tubes in the series. From the last return bend it is discharged into the body of the evaporator, where it is boiled by the 2-in. tubes as in an ordinary horizontal evaporator. It is possible in the operation of this machine to separate the inside tubes from the outside tubes and thus a very wide range of interesting problems is opened up.

CONDENSATE RECEIVERS

The whole subject of the basis for reporting the results of the station has been given careful consideration, and it has been decided to base all work on the actual heat transmitted rather than on amount of liquid evaporated. The latter plan obscures the results by introducing such factors as temperature of feed, loss by entrainment, radiation, etc. All these may be determined when desired; but the fundamental work is based on heat transmitted. Therefore the primary

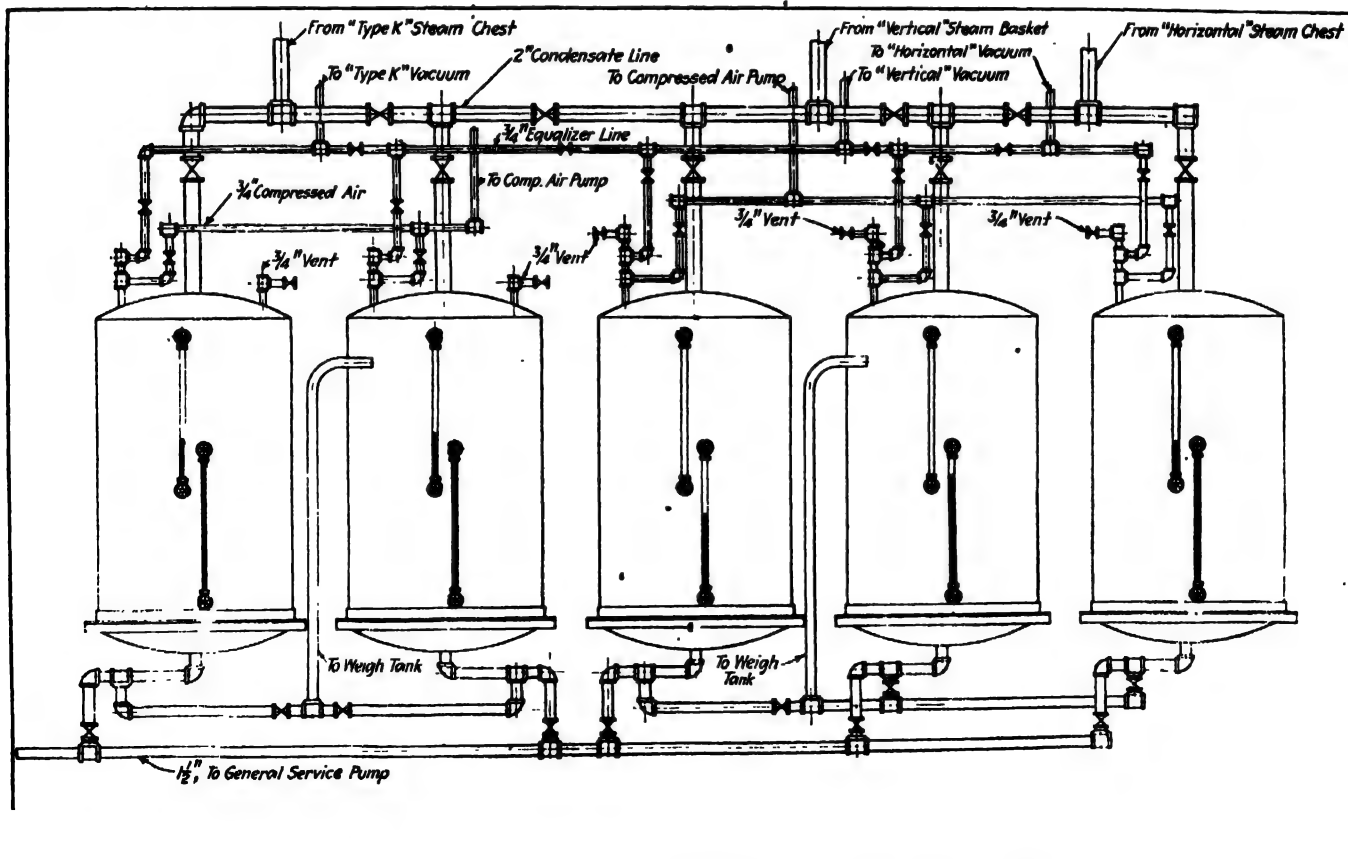

FIG. 6. ARRANGEMENT OF CONDENSED WATER RECEIVERS

FIG. 7. WORKING PLATFORM; CONTROLS ON VERTICAL TUBE EVAPORATOR

measurement is the weight of steam condensed in a given time.

This is determined by collecting the condensate in receivers (see Fig. 6) in which it may be measured or from which it may be removed and weighed. There are five of these sheet iron tanks 30 in. in diameter, 48 in. high, with heavy cast-iron bottoms and sheet-iron heads. They are all connected into a 2-in. header. Into this header come connections bringing the condensate from the various evaporators. The headers and their valves are so arranged that all the evaporators may run at the same time or more than one receiver may be provided for runs where large amounts of steam are condensed.

In order to vent these receivers and also to remove non-condensed gases, each receiver has a $\frac{1}{2}$ -in. vent connected to a $\frac{1}{2}$ -in. header. This header in turn has three $\frac{1}{2}$ -in. vent lines, each with throttling and blow-off valves, running one to each evaporator. Suitable valves make it possible to vent any receiver to any evaporator. These vents, during a run, are throttled down to the point where they just serve to keep the steam space clear of non-condensed gases.

A header delivers compressed air to each receiver. The bottom outlets have two headers. One delivers to a gooseneck which discharges into a weigh tank, the other leads to the general service pump. Each receiver has carefully calibrated gage glasses and a thermometer for calculating density corrections to the calibrations. During a run the condensate level is noted at the beginning and at the end. The quantity may be calculated from the calibration; or compressed air may be turned in and the condensate blown over into the weigh tank. This latter method, of course, can be used only when the condensate is below 100 deg.

In spite of the large size of the equipment and its

complexity, a highly centralized control system has been developed. From the working platform 7.5 ft. above the floor, one man can operate each evaporator and take all necessary readings. Steam, feed, condensate, vent and all other valves may be reached from one position, immediately in front of the manometer board. The condenser and vacuum pump are also controlled from this floor. Fig. 7 shows the controls on the vertical evaporator, and Fig. 8 on the horizontal.

All pressure measurements are made with mercury manometers connected by seamless copper tubing to the point where pressure is to be determined. All manometers for one evaporator are collected on a manometer board near the controls. Temperatures are measured by calibrated thermometers, protected by iron pipe guards. All measurements are taken in the metric system; partly because accurate laboratory apparatus is usually metric, partly because of simplicity of calculation, and partly because practically all of the literature on evaporator design is in German and hence comparisons with previous work are easier if results are in metric units.

Early in the work it was found that maintaining an accurately controlled vacuum was rather difficult. A vacuum regulator was devised which has been very satisfactory (see Fig. 7). A $\frac{1}{2}$ -in. pipe is led from the top of the vapor space to the instrument board and carries a Crane needle valve opening to the air. It also carries a special needle valve with no stuffing box around the stem. This stem is prolonged and is connected to a bar of soft iron which forms the core of a solenoid. An iron wire is immersed in the mercury in the open arm of the vacuum manometer. A brass rod ending in a platinum tipped wire passes through a stuffing box into the high side of the vacuum manometer. This rod is threaded and its position may be very accurately adjusted by a milled nut in a small bracket on the instrument board. The vacuum pump is run a little faster than necessary to maintain the desired vacuum. As the mercury in the vacuum manometer rises and reaches the desired point, it makes

FIG. 8. WORKING PLATFORM; CONTROLS ON HORIZONTAL TUBE EVAPORATOR

contact with the platinum tipped brass rod and thereby closes a circuit through an ordinary telegraph relay. This relay closes a 220-volt circuit through the solenoid, opens the needle valve and bleeds air into the vapor space of the evaporator until the vacuum falls to the desired point. The second needle valve above mentioned is set by hand to give an approximation and the regulator is thus left to take care of only minor fluctuations. The device has worked very satisfactorily and will usually hold the vacuum to within 2 mm. for an indefinite length of time. Occasionally the strokes of the vacuum pump become synchronized with the natural period of vibration of the mercury, which produces regular surges in the manometer with a slight decrease in the accuracy of regulation.

An upper platform, 15 ft. above the floor, is provided for giving access to the upper parts of the evaporators. Weigh tanks and feed tanks, one of each for each evaporator, are located here. When desired, the feed may be weighed, but, as discussed later, this is not often necessary. This obviates maintaining an operator on the upper floor during a test. The station is surrounded by a balcony at this level connecting with these upper platforms and with the office.

GENERAL EQUIPMENT

The station is served by a 1½-in. class "C" Worthington volute pump. By means of a manifold on the suction and another manifold on the discharge this pump performs practically all the work of the station. One ring discharge main extends around the station connecting with all the storage tanks and evaporator feed tanks. The common suction line is not a complete ring, but includes all the storage tanks on one side and all the evaporators on the other side. There are a number of separate connections besides these two principal mains. A Marsh 3 x 5 x 8 magma pump is connected into the suction line and into the ring main; and valves are so placed that it may be used either as a substitute for the general service pump, or operated in parallel with, but independent of, the general service pump.

The three condensers unite in a cross and the fourth outlet of this cross is connected to an American-Marsh 8 x 10 x 12 vacuum pump. Valves are placed in the lines to the condensers so that evaporators not in use can be completely cut off. This pump and the magma pump mentioned before are a gift to the laboratory from the American Steam Pump Co. of Battle Creek. A small direct steam driven air compressor furnishes air at 25 lb.; city water at 60 lb. and 220-volt direct current are furnished from the university mains. The floor of the station is below the sewer. Waste water is consequently discharged into a sump, from which it is lifted by a Worthington Duplex 5½ x 4½ x 5 tank pump, the gift of the Henry R. Worthington Co. The station also has a 10-in. experimental centrifugal (see Fig. 1), loaned by the American Tool & Machine Co., and a No. 2 Sweetland filter, loaned by the United Filters Co. A crystallizer, a steam-jacketed still, and additional transfer pumps will be added in the immediate future. A Tagliabue liquor level regulator loaned by the Tagliabue Manufacturing Co. has simplified the experimental work on the vertical tube evaporator.

PROGRAM

The work of the station falls into two very distinct classes. The first, by far the most important, is the class of purely theoretical investigations into the

principles of evaporator design. Two papers, the first results of this program, are being presented herewith.¹ These two deal with the vertical tube evaporator because the staff of the station has been insufficient to keep work going continuously on all three evaporators. A great deal has already been done on the horizontal tube evaporator and the "Type K" evaporator, but no results are ready for publication from these machines. The program of problems already outlined involves over sixty separate questions, illustrations of which are the problems already mentioned in connection with the vertical tube and horizontal tube evaporators. It is hoped that it will be possible to publish a continuous series of papers along these lines; and the volume of work so available depends primarily on the growth of graduate work in the chemical engineering department of the University of Michigan.

The second class of work in which the station is engaged is in the solving of concrete problems regarding the development of a particular process or the evaporation of particular solutions. As a sample of the types of problems already handled may be mentioned the following: The production of high-grade table salt from dilute brine carrying much larger amounts of calcium and magnesium chlorides than is considered practical in ordinary salt manufacture; the preparation of a high-grade potash salt from an impure Western brine carrying sulphates, chlorides and carbonates of both potassium and sodium; the evaporation of dextrine sirup to high concentration; the design of a lead evaporator for the manufacture of aluminum sulphate, etc.

The station was originally planned to study evaporators only and consequently no accessory apparatus such as filters, centrifuges, etc., was planned. The size and scope of the concrete problems which have come up have made necessary a revision of this plan, and it is intended now to extend the equipment of the station until there will be in existence a complete chemical plant with all its units on the scale of the evaporators. This will mean that complete processes can be worked through in ton lots. It takes at least 1,000 gal. of a solution to make a satisfactory test so far as the evaporators are concerned. This station is not interested in the working out of new processes on the usual chemical laboratory scale, as there are other organizations much better fitted to handle that class of research work, but we are interested in the working out, on a commercial scale, of processes already established in a chemical laboratory.

Interesting though these specific problems are, it is not intended that they shall ever displace the principal purpose for which the station was founded, which is the study of the underlying principles of evaporator design and through them the extension of our knowledge of the whole phenomenon of heat transmission from steam to liquids.

Chemical Engineering Department,
University of Michigan,
Ann Arbor, Mich.

Cement Factory Opened in Chosen (Korea)

The Onoda Cement Manufacturing Co., of Japan, which was formally opened at Pyongyang, Chosen, in May, is reported to have a capacity of 60,000 tons of cement a year, making it one of the biggest factories of the kind ever established in that country.

¹ These papers will be published in subsequent issues of this journal.

Current Events

in the Chemical and Metallurgical Industries

Important Sections Planned for Chemical Exposition

The Sixth National Exposition of Chemical Industries, which is to be held at Grand Central Palace, Sept. 20-25, plans many innovations, among which are sections on Fuel Economy, Materials Handling, Chemical Engineering and Industrial Management. Arrangements have been made for the presentation of papers by eminent men in the profession on important topics in these sections according to the following tentative program:

FUEL ECONOMY

Fluid-Heat Transmission H. B. McKechnie
Refractory Cement—Life Insurance for
a Furnace F. W. Reisman
Producer Gas and Modern Mechanical
Producer W. B. Chapman
Preventing Conduction and Radiation
Heat Waste S. L. Barnes
Powdered Coal W. O. Rankin
American Dressler Tunnel Kilns C. Dressler

MATERIALS HANDLING

Chain Belt Transmission F. G. Anderson

CHEMICAL ENGINEERING

Nitration H. Hough and W. Savage
New Methods of Destructive Distillation
..... T. W. Pritchard
Corrosion and Galvanic Action in the
Industries W. D. Richardson

INDUSTRIAL MANAGEMENT

Ultra Analysis of Costs H. E. Ernst
Research in Industrial Conservation H. E. Howe

There will be a wide range of exhibits this year. The fact that the Exposition has been divided into sections has caused greater interest than ever and the Materials Handling Division and the Fuel Economy Division, both of which will be new this year, have attracted many large concerns.

As in the past, moving pictures will be a part of the general program. Several new reels depicting various important chemical and mining industries have been arranged for.

The Materials Handling Section will embrace exhibits of machinery and equipment, and will be interesting to manufacturers because every industry must at some stage of its business convey its products from the place of its manufacture to the place of its consumption. Raw material must also be handled, and with the scarcity of man power, machinery promises to be a big factor in the future. It is expected that this section will enable the manufacturers to see the economy as well as the efficiency of machinery in the matter of conveying material.

The Fuel Economy Section is important in view of the high price and the increasing cost of coal. In the section will be shown machinery and apparatus, furnaces, producers, stokers and all devices that tend to the economical utilization and the more efficient combustion of fuel.

With the majority of the exhibits tending along the

lines of progress and economy it is evident that a visit to the Exposition will benefit manufacturers and business men. Impressions not to be gained elsewhere which will be valuable in the future will be stowed away; for a glance into the inside of chemistry has been known to bring improved conditions in many industries and manufacturing plants.

Columbia University Offers Six-Year Course in Engineering

To meet the more exacting demands required of men in the engineering profession today, the faculty of Columbia University has arranged a 6-yr. course for would-be engineers. There is a feeling at present among some men that engineers as a whole are not as well educated as other professional men. Columbia, realizing this, is trying to solve the problem by lengthening the engineering courses to six years, three of which will be devoted to general education and three to specialized work.

The first three years are devoted to the study of mathematics through differential and integral calculus, elementary differential equations, general chemistry and qualitative analysis, general physics, drawing and the humanities. This curriculum, together with the general exchange of ideas through contact between fellow-students from all parts of the civilized world, will give the men greater opportunity to broaden out than is possible in a 4-yr. course.

After the general college course, it is expected that the student will apply all his energies seriously to perfecting himself in the line of endeavor he expects to make his life work, and all the courses are arranged with this end in view, particular emphasis being laid on the further study of subjects pertaining to mining, metallurgical, civil, electrical, mechanical and chemical engineering, and leading to degrees in these professions.

Such an arrangement will not only broaden the men, but will raise the standard of their profession, for by the law of the survival of the fittest the tendency would be for only such men as have the necessary qualifications to stick and complete their course.

Bureau of Mines Seeking Site for Experiment Station

Five cities in the South believe they are especially qualified for the site of the new non-metallic experiment station which is to be established by the Bureau of Mines. They are Chapel Hill, N. C.; Atlanta, Ga.; Birmingham, Ala.; Tuscaloosa, Ala., and Knoxville, Tenn. Dorsey A. Lyon, supervisor of stations for the Bureau of Mines, and Dr. R. B. Moore, its chief chemist, have recently been in the South, checking up the claims of each of the cities mentioned.

In effect, the new station will be a chemical station, since it is the chemical industries that have the greatest interest in non-metals.

Preliminary Program for Chicago Meeting of the American Chemical Society

The Sixtieth Convention of the American Chemical Society to be held with headquarters at the Congress Hotel, Chicago, Sept. 6 to 10, 1920, promises to be a most successful meeting as shown by the plans so far developed by the Executive committee of the Chicago Section.

On Monday noon the Chicago Chemists' Club will entertain the directors and officials of the national society at luncheon. The councillors will convene about 4 p.m. on the same day and adjourn at 6:30 to be entertained by the Chicago Section at dinner. This meeting will be re-called at 8 p.m. to continue with the business of the Society.

Tuesday morning the general addresses will start downtown, and after luncheon will be reconvened at the Patten Gymnasium, Northwestern University, Evanston, about 2 p.m. About 4 p.m. the evening entertainment will start. This will be a marked departure from the time-worn smoker, permitting the attendance of the ladies, and consisting of a beach party, picnic supper, athletic contest, college reunions, musical program outdoors, and a special program in the gymnasium after 8 p.m.

Under the towering elms of the campus, on the shores of Lake Michigan, the band concert will continue until 7:30 p.m. Refreshments will be served, and baseball games held between teams to be later announced. The beach of Lake Michigan is a beauty spot which will attract many from the other entertainments during this period. Rowboats will be furnished. The swimming tank in the gymnasium will be open for men. An organ concert will be given in Fisk Hall, from 4:30 to 6 p.m.

A special feature of the outing will be the decoration of the campus with the colors of the American Chemical Society, college banners, chemical fraternity pennants and the colors of other chemical organizations to serve as nuclei and stimulate many reunions. The entertainment committee will provide a booth at which reservations can be made by such groups as desire to sit together at supper. This picnic supper will be served at tables in another portion of the large campus.

The entertainment program, given indoors at 8 p.m., is veiled in mystery as to details. In case of inclement weather all events will be carried out in the mammoth gymnasium, which has several halls large enough to accommodate many times more than will be present.

Other social features provided during the week are entertainments for the ladies and the banquet on Wednesday night. This banquet will be at the Congress Hotel and the program embraces a songfest, timely speeches and numbers by noted opera singers. For the ladies Miss Ethel M. Terry, chairman of the committee, promises an automobile trip, a specially guided tour of the Chicago Art Institute, dinner for the professional women and many alternative excursions. These plans are in addition to the general entertainments which the ladies will attend. There will be a hostess lady for every visiting lady.

DIVISIONAL MEETINGS

While the headquarters of the convention are to be at the Congress Hotel, arrangements have been made to hold all divisional meetings at the University of Chicago. Facilities are there available for lanterns, blackboards

and auditoriums with fine acoustic properties such as will make this work a real pleasure. Luncheons are to be provided at the Edelweiss Gardens, a five-minute walk from the buildings. Thursday and Friday will find the visitors then in an atmosphere appropriate to the true purpose of the convention.

VISITS TO INDUSTRIAL PLANTS

On Wednesday afternoon the members will assemble at the Van Buren St. station of the Illinois Central for a visit to the plants of the Sherwin-Williams Paint Co., the Carter White Lead Co., Libby, McNeil & Libby canning plant, the Pullman Car Co. and the Doehler Die Casting Co. Friday morning the works of the Grasselli Chemical Co., the U. S. Lead Refining Co. and the American Maize Products Co. will be inspected, while the afternoon trip will include the Crane Co.'s gray-iron foundry, the Fansteel Co., tungsten products, the Lindsay Light Co. and the Carnotite Reduction Co. plants.

The executive committee of the Chicago Section in charge of the work is composed of the following members: W. Lee Lewis, chairman; F. M. DeBeers, Convention treasurer; R. J. Quinn, Convention secretary; Julius Stieglitz, honorary chairman; W. A. Converse, finance; Chester H. Jones, publicity; H. McCormack, excursions; G. H. Pichard, registration and information; S. L. Redman, hotels; A. E. Schaar, transportation; J. A. Hynes, program; D. K. French, banquet; Herbert N. McCoy, men's entertainment; Ethel M. Terry, ladies' entertainment; William Hoskins, relation to other scientific societies.

Chemical Industries Protest Coal-Tar Priority

While the chemical industries were not represented among those who appeared before the Interstate Commerce Commission to protest against allowing coal mines to have prior claim on open-top cars, the Commission has received many informal complaints from chemical industries, as much of their raw material is moved in that class of equipment. The Commission recognizes that much hardship and great losses are being occasioned by its various orders giving priority to the movement of coal, but feels that it is absolutely necessary to concentrate on coal transportation to the exclusion of most other commodities. This is due largely to the fact that coal can be moved with so much greater facility in the summertime as to constitute a great saving of cars. It is believed that if coal is moved in maximum quantity, up to Sept. 1, the worst of the situation will have been surmounted. After that time, it seems probable, other industries will be able to have their normal proportion of cars.

The decision of the Railroad Labor Board is expected to have a very immediate effect on efficiency in transportation. It is apparent that the Commission is fully determined to stand by its priority orders, despite the great pressure which has been exerted to secure their modification. It was evident that the Commission was most impressed by the complaint that the so-called non-essential industries are being allowed the use of a large portion of the supply of open-top cars which are used in transporting their coal supply, while the chemical industry, the building industries and the maintenance of highways are practically denied any use of this class of railroad cars. The difficulty is that the Commission does not feel that it has the authority to discriminate between essential and non-essential industries.

Industrial Relations Association Elects Officers

J. M. Larkin, assistant to President E. G. Grace of the Bethlehem Steel Co., Bethlehem, Pa., will direct the destinies of the Industrial Relations Association of America for the coming year. He was the unanimous choice of the members of the board of directors at the annual reorganization meeting at Atlantic City. Mr. Larkin is ably qualified for the place, being one of the few industrial relations men of the country who have been given recognition as such by a seat on the board of directors of his company. His handling of the representation plan in effect at the plants of both the Bethlehem Steel Co. and the Bethlehem Shipbuilding Corporation has won him the highest esteem, of both the company and the workers.

Mark M. Jones, director of personnel of the Thomas A. Edison Industries, whose resignation as executive secretary was received and accepted to be effective Sept. 15 at the latest, was elected vice-president. A change in the constitution of the organization is being planned to allow the election of six other vice-presidents, each one of whom will be assigned to a specific territory.

F. C. Parker, executive officer of the Central Y.M.C.A., Chicago, and secretary of Chicago Council, Industrial Relations Association of America, was elected secretary for the second time.

W. H. Winans, of the Union Carbide & Carbon Co., New York City, was elected treasurer. For the present the administrative offices will remain at Orange, with E. A. Shay, the assistant secretary of the association, in charge. A meeting of the board of directors will be held in Buffalo on July 30 to formulate a program for the coming year and to elect a successor to Mr. Jones.

The administrative offices are now engaged in preparing for publication the proceedings of the Chicago convention in May, at which between 2,000 and 3,000 industrial relations workers and executives of all classes were in attendance.

Program of Fall Meeting of T.A.P.P.I.

On Sept. 1 to 3, 1920, the fall meeting of the Technical Association of the Pulp and Paper Industry will take place at Saratoga Springs, N. Y., with headquarters at the Grand Union Hotel. The program gives assurance of a most interesting and instructive meeting.

The business session will open on Wednesday morning, Sept. 1, at 9:30 o'clock, in the Casino. Officers' and committee reports will be presented, followed by papers on special subjects, an especially important one being on the Washing of Felts. In the evening members and guests will be entertained at dinner by the paper manufacturers of the Hudson River Valley and vicinity. The speakers thus far selected include C. R. McMillen, of the Union Bag & Paper Corporation, who will act as toastmaster; Philip T. Dodge, of the International Paper Co., and Colonel C. H. L. Jones, of the Spanish River Pulp & Paper Mills, Ltd.

Thursday, Sept. 2, will be given up to mill visitations, followed by a steamboat excursion on Lake George in the evening. It has been arranged to pay visits of inspection during the day to the plants of the International Paper Co., Finch, Pruyn & Co., Union Bag & Paper Corporation, Standard Wall Paper Co. and Sandy Hill Iron & Brass Works. Automobiles will be provided to convey the members to and from the places visited.

On Friday the members of T.A.P.P.I. and their guests will be taken to the works of the General Electric Co., at Schenectady, where the machinery and electrical

apparatus used in pulp and paper mills will be shown in the making. The visitors will subsequently be the guests of the General Electric Co. at luncheon. In the afternoon it is planned to visit the felt mills of F. C. Huyck & Sons and the Albany Felt Co.

T.A.P.P.I. asks the pulp and paper manufacturers who are represented by membership in the association to take a broad and generous view of this gathering of the technical men of the industry and arrange for a good attendance on the part of members connected with their mills, or of prospective members. The stated meetings of T.A.P.P.I. afford valuable opportunities for the discussion of common problems, new developments, methods and processes, and it is hoped that mill executives will appreciate the advantages to be derived from their technical advisers coming in personal contact with the engineers and chemists of other mills in this way.

Chemical Warfare Service and Charcoal

Due to the fact that private concerns at Columbus, Ohio; Elizabeth, N. J., and Cleveland, Ohio, are conducting important researches in connection with the utilization of charcoal for chemical purposes, the Chemical Warfare Service has suspended temporarily that portion of its research work. This is done to avoid possible duplication of effort. Later, the Chemical Warfare Service expects to take up experiments with the synthetic charcoals made from coal and coke.

General A. A. Fries, chief of the Chemical Warfare Service, is gathering many important data regarding special uses of charcoal. Since the efficiency of the gas mask depends upon certain classes of charcoal, the Chemical Warfare Service expects to keep in very close touch with all developments in that connection. Just at present, General Fries is greatly interested in the development of an excellent charcoal from rice husks. The rice husk contains a great deal of silica and as a result, when properly burned, does not powder into a lampblack. During the war it was found that the charcoal made from coconut shell was best suited for use in gas masks. Cohune nut charcoal and peach pit charcoal came next in respective desirability. As yet no better substitutes have been found, but experiments are planned which will take up the matter of impregnating charcoals with chemicals which will add to their efficiency in neutralizing gases.

General Fries will request an appropriation at the next session of Congress which will enable him to add several civilian chemists of ability to his staff. At present the chemists needed in the service must be drawn from the Army. It is the desire of General Fries to supplement his staff of military chemists with several civilian chemists who have specialized in the subjects of greatest interest to the Chemical Warfare Service. This need will be met in the meantime by the appointment of consulting chemists who will be willing to give a limited amount of time to the problems of the Service, in connection with their regular work. They will be paid a nominal salary. The first consulting chemist to be appointed is Dr. E. E. Reed, of Johns Hopkins. Other appointments will be made soon.

Quebec Pulpwood Embargo to Stay

It is announced officially that the Quebec Government has no intention of raising the embargo on the export of pulpwood as has been demanded by American interests.

Bakelite Used for Airplane Propellers

A series of tests with Bakelite propellers has recently been completed by the Army Air Service. The results are reported to have been satisfactory. Several designs of propellers were used, but the micarta construction was more serviceable. These propellers were made by coating sheets of duck with Bakelite, then pressing five or six of these sheets tightly together to form a board that is sawed out in the shape of a propeller lamination just as wood laminations are cut. The Bakelite is then molded to an exact angle in a special mold under pressure at 350 deg. F.

The advantages discovered in the Army tests are: Uniformity of texture; strength; absence of warping; elasticity; absence of metal hub; uniformity of all propellers made from the same mold; proof against abrasion; proof against moisture, including oil; freedom from checking and splitting; adjustable pitch feature, resulting partly from elasticity; ease and rapidity of manufacture, once the molds are completed.

Shortage of Chlorine Affects Purification of Water Supply

Complaints of short supplies of chlorine and other chemicals used in water purification have reached the Interstate Commerce Commission from several sources. It is the opinion of Dr. R. B. Moore, chief chemist of the Bureau of Mines, that these shortages are chargeable mainly to the transportation situation, but he calls attention to a general tendency on the part of chemical manufacturers to overestimate the length of time that stocks accumulated during the war will last. The fact that stocks frequently are overestimated and that consumption is greater than is realized has resulted in great scarcity in several chemicals. Stocks become low before the manufacturing of new supplies starts, with the result that shortages become acute before production catches up with demand.

Retirement of Government Scientists

The only member of the scientific staff of the U. S. Geological Survey who will retire at an early date under the recent act for retirement of Government employees is T. Nelson Dale, geologist. Mr. Dale has been for a long period on the geological staff of the Survey, engaged particularly in economic geology studies of slate, granite, marble, etc.

Dr. F. W. Clarke, chief chemist, and William H. Dall, geologist and paleontologist, are of retirement age, but under the provisions of the act will be retained in active service for an additional period.

None of the members of the scientific staff of the Bureau of Mines is affected by the provisions of this act for retirement. Similarly none of the scientific men at the Bureau of Standards will be retired.

Shortage of Motor Fuel Serious

The gasoline shortage in the Pacific Northwest is rapidly becoming acute. For the past month it has been with difficulty that the three large oil companies operating in that territory have been able to provide sufficient gasoline for the most necessary of occupations. The rationing system has been in effect for a month and in general has limited trucks to purchases of ten gallons and pleasure cars to tankfuls of three gallons. Only vehicles operated by fire and police departments

and doctors have been able to secure unlimited supplies. The Standard Oil Co., Shell Co. and Union Oil Co. do not offer any hope for permanent relief from the shortage until in the middle of the summer at the very earliest with possibilities that strict economy will be necessary until next fall. The reasons ascribed to the shortage, are insufficiency of supply of the oil obtainable in California oil fields. Besides affecting hundreds by shortage of the gasoline supply, the lack of fuel oil is also embarrassing a great many manufacturers in that since they are equipped to burn fuel oil, it is with difficulty that they are able to rapidly make changes that will provide for coal burning. It is possible that the ultimate solution for this latter situation may be the substitution of powdered coal or producer gas.

Chemical Exports and Imports During May

Exports of chemicals during May, 1920, were valued at \$18,357,237. This is nearly double the value of the chemicals exported in May, 1919. Some of the items making up the total, as well as revised figures for May, 1919, are as follows:

	May, 1919 Lb.	May, 1920 Lb.
Acids:		
Carbolic.....	130,457	420,274
Nitric.....	17,890	99,359
Picric.....	88	53
Sulphuric.....	1,627,860	2,655,432
Benzol.....	70,482	1,484,630
Calcium carbide.....	2,883,309	1,452,955
Copper sulphate.....	861,168	461,916
Line:		
Acetate of.....	97,017	4,425,267
Chloride of (bleaching powder).....	1,752,352	5,560,938
Chlorate of potash.....	57,380	235,130
Value.....		
Total sodas.....	\$927,600	\$2,702,473
Total chemicals.....	9,733,513	18,357,237
Total dyes and dyestuffs.....	954,943	3,377,885
Medicinal and pharmaceutical preparations.....	1,523,784	2,305,718

Some of the import figures, as compiled by the Bureau of Foreign and Domestic Commerce, are as follows:

	Lb.	Lb.
Acids (except coal tar acids)		
Oxalic..... (duty)	none	6,406
All others..... (duty)	266,791	490,926
Free.....	4,260,288	1,896,921
Chemical and medicinal compounds:		
Alkalies, alkaloïds and preparations, mixtures of..... (duty)	418,731	277,661
Medicinal preparations..... (duty)	84,473	150,293
Value.....		
Total coal-tar products.....	\$737,909	\$634,840
Total gums.....	2,520,843	5,714,192
Total chemicals, drugs, dyes, etc.....		
Free.....	4,534,508	15,734,604
Duty.....	6,229,522	3,286,458

Re-exported chemicals, as compiled by the Bureau of Foreign and Domestic Commerce, are:

	1919 Lb.	1920 Lb.
Acids:		
Carbolic.....	none	none
Oxalic.....	none	11,540
All other.....	7,204	74,415
Extracts and decoctions for tanning:		
Quebracho.....	21,442	566,419
All other.....	none	971,196
Gums:		
Camphor, crude, natural.....	264	13,431
Camphor, refined and synthetic.....	2,623	19,448
Copal, dammar and kauri.....	98,677	160,719
Gambier, or terra japonica.....	none	16,503
Indigo, natural or synthetic.....	14,014	74,453
Iodine, crude or resublimed.....	none	none
Licorice root.....	372	none
Opium, containing 9 per cent and over of morphia.....	789	41,538
Carbonate of potash.....	none	none
Nitrate of soda.....	none	none
Value.....		
Total chemicals, re-exported.....	\$222,443	\$1,052,878

Movement to Form Chemical Warfare Service Association

A movement is under way to establish a Chemical Warfare Service Association. Qualifications for membership will not be restrictive and anyone who is particularly interested in the work being performed by the Service will be eligible.

More Swiss Dyes Here

Another large consignment of Swiss dyes, consisting of 13 casks, 4 barrels, 115 packages, 90 cylinders and 5 cases, arrived the first week in July from Havre. It is understood that these assorted colors will be disposed of in the same way as former consignments, without disturbance to the local market. Further shipments from the same source are expected and arrangements have already been made for allotments to the consuming trade.

It is not expected that these foreign products will interfere in the slightest degree with the market for American colors; in fact there is a tendency to welcome the relief thus afforded from the pressure brought to bear on the manufacturers.

Railroad conditions are still retarding business, but the most serious handicap thus far experienced has been the shortage of coal at plants. This has already resulted in the shutting down of one New Jersey plant and curtailment of operations at others.

Additions to Columbia University Metallurgical Laboratory

In addition to the equipment of the Columbia University metallurgical department, in the ore-dressing laboratory, which was installed by Prof. H. S. Munroe, now retired, there is being added, under the direction of Prof. Arthur F. Taggart, a Hardinge conical mill, a Dorr classifier, a Dorr thickener, a Deister-Overstrom concentrating table with interchangeable decks, flotation equipment to demonstrate different successful flotation processes, and considerable accessory equipment such as microscopes, polariscopes, refractometers and viscosimeters. Additional motors are also being provided to drive this machinery. These changes and additions have been made possible by the generosity of machinery manufacturers and of individuals and mining companies who have contributed money.

Executive Committee Meeting of the Manufacturing Chemists Association

The regular monthly meeting of the executive committee of the Manufacturing Chemists Association was held at the India House, New York City, Wednesday, July 21. The session was called to order by Chairman Henry Howard of the Grasselli Chemical Co. The committee voted favorably on the merchant marine bill and expressed hope that it would help the export business. The Chamber of Commerce referendum No. 31 was also favorably received.

In co-operation with the Bureau of Explosives the test committee is working out standard tests for carboys to reduce the percentage of breakage in transportation. This work is being carried on at the Grasselli Chemical Co.'s plant in New Jersey.

Rubber From Candleweed

The plant of the Ocotillo Products Co. at Salome, Ariz., has started operations and is producing a ton of crude rubber per day from the ocotillo, or candleweed, which grows wild in great abundance in that section. The product is said to vulcanize satisfactorily and to act in every way like rubber. One ton of ocotillo yields 200 lb. of gum and 90 lb. of a tarry product which is marketable.

The company was organized in Indianapolis, Ind., but will establish permanent offices in Los Angeles.

Bureau of Mines to Assist in Power Survey

O. P. Hood, chief mechanical engineer of the Bureau of Mines, will be a member of the principal engineering staff in connection with the superpower investigations of the U. S. Geological Survey. Mr. Hood presumably will be directly in charge of those aspects of this power development work which relate to coking of coal and efficiency in fuel utilization. He will be responsible for tying up the Survey superpower study with the related investigations of the Bureau of Mines, most of which are under his direction. This development is directly in line with the editorial comment made in this journal recently, referring to the possibility of coking coal and augmenting the supply of byproduct gas in lieu of developing electric power and building transmission lines. It indicates that the problems emphasized as important from an industrial-chemical point of view will receive that attention which they deserve, as Mr. Hood is intimately acquainted with these.

Book Reviews

ELECTRIC FURNACES IN THE IRON AND STEEL INDUSTRY. By W. Rodenhausen, J. Schoenwa and C. H. Vom Baur. Third edition, 1920. New York: John Wiley & Sons; London: Chapman & Hall, Ltd.

Electric Furnaces in the Iron and Steel Industry contains considerably more information descriptive of electric iron and steel furnaces and more electrometallurgy of iron and steel than any other book which has been published on the subject. The book is written in a somewhat German style, and contains considerable descriptive matter which the average technical reader might not consider necessary. The arrangement of the book would be improved if the information in the two chapters of Part II—materials used in furnace construction, and the electrometallurgy of iron and steel—was placed where the subjects are first discussed in Part I. This is especially true of the electrometallurgy of iron and steel, as a reader familiar with the subject finds considerable data lacking when he reads the discussion on electric furnace pig iron in Part I. Too much space has been allotted to the induction furnace. The induction steel furnace may have considerable standing in Germany, but it has none in the United States, where interest in it is largely of a historical nature. An excellent feature is the inclusion of basic electrical information on which the design and operation of electric furnaces is dependent. Considering the fact that Heroult electric steel furnaces have been installed in considerably greater number than any other type of electric steel furnace, not enough space is devoted to this furnace. The value of the book would be increased by discussion of processes to a greater length, including manufacture of steel castings, alloy steel, acid steel and basic steel, and giving more actual operating detail for use of the furnace operator. A new development covered briefly is the production of synthetic pig iron from steel turnings in Canada. It is to be regretted that the book went to press a little too early to include the results of Keller on production of synthetic foundry iron. An important subject not mentioned is the heat treatment of steel in the electric resistance furnace, a phase of electrometallurgy which has had a great development during the past three years.

Except for the following additions there are few changes in the text from that of the 3rd edition, 1917: Seede electrode regulator, Greene furnace, Moore furnace, Booth-Hall furnace, Vom Baur furnace, Ludlum furnace, pig iron from steel turnings, and duplexing with the cupola. Although the arrangement of the book is not the best, and there are several important omissions, the book contains a large quantity of information and is the most up-to-date publication on the subject.

ROBERT M. KEENEY.

Personal

Dr. CHARLES FREDERICK CHANDLER received the honorary degree of Doctor of Science at the recent commencement exercises at Union College. In conferring the degree, Dr. Charles Alexander Richmond, chancellor of the university, spoke briefly as follows: "Charles Frederick Chandler, educated at Lawrence Scientific School, Harvard University, and at the Universities of Berlin and Göttingen; professor of chemistry at Union College, 1857-1864; one of the organizers and for many years dean of the School of Mines of Columbia University; author of many chemical papers; member of many scientific and learned societies both here and abroad; the recipient of distinguished academic honors from universities in America and England; esteemed by your profession, beloved by generations of grateful students to whom you have imparted both knowledge and wisdom, we delight also to do you honor. *Honoris causa*, I admit you to the degree of Doctor of Science and direct that your name be enrolled among the honorary sons of Union College."

M. J. GAVIN, refinery engineer for the U. S. Bureau of Mines, with headquarters at Salt Lake City, visited the San Francisco office of the Bureau during June, in connection with oil-shale development.

DAVID JONES, who holds an 1851 exhibition scholarship (from London University) at Johns Hopkins University, is now connected with the chemical division of the Eastman Kodak Co.'s research laboratory.

Dr. R. B. MOORE, chief chemist of the Bureau of Mines, and DORSEY A. LYON, its supervisor of experiment stations, have returned from an inspection visit to the various points in the South which are under consideration as sites for the new non-metallic mineral station. It is expected that the selection will be announced within a week.

JAMES T. NEWTON, Commissioner of Patents, has tendered his resignation to the President, which was effective July 19. No official report that the President had accepted has been received, but it is understood that he will. Commissioner Newton expressed great reluctance at leaving the office after thirty years' Government service, and mentioned the inadequate salary of \$5,000 a year among his reasons for resigning.

Dr. HARRISON E. PATTEN has recently resigned as research chemist of the Bureau of Chemistry, Department of Agriculture, to accept an appointment as chief chemist of the phosphate plant of the Provident Chemical Works, St. Louis, Mo.

A. B. PORTMAN has recently been appointed assistant sales manager of acids and heavy chemicals for the Monsanto Chemical Works at St. Louis, Mo., vice John W. Carroll, who has been transferred to higher duties.

F. L. RIGHTER, a Leland Stanford University graduate, who during the past year has been doing graduate work in the chemistry department at Cornell University, has joined the staff of the research laboratory of the Eastman Kodak Co., Rochester, N. Y.

L. D. VORCE has severed his connection with the Canadian Salt Co. to take an active part in the business of the Precision Instrument Co., Newark, N. J.

Obituary

FRED S. BRADLEY, son of Peter B. Bradley, president of the American Agricultural Chemical Co., died on July 5. Mr. Bradley was manager of the Jacksonville, Fla., branch of the company. His death was the result of the collapse of the wheel of the automobile he was driving on the beach at Jacksonville.

Current Market Reports

The Iron and Steel Market

Pittsburgh, July 23, 1920.

The iron and steel market has become still more inactive, conditions bordering almost on stagnation. There is some buying, but it is only of material that the buyer is assured he will need in the very near future, or is in the nature of covering requirements in the distant future with the Steel Corporation. In other words, buying of steel products is for very late delivery, the first or second quarter of next year in the case of the Steel Corporation, and is only for very early delivery in the case of the independents. The difference in policy is of course due to the difference in prices quoted. In the matter of pig iron, there are occasional instances reported in other districts of small purchases for late delivery, but in general the buying of pig iron is only for very early shipment, and usually by consumers who are already covered by contract but are not getting deliveries.

TRANSPORTATION CONDITIONS

The common testimony is that transportation conditions, as regards the supply of cars for loading at blast furnaces and steel mills, have grown worse in the past week. An exception is the Chicago district, where, it is said, a little of the accumulated steel has been moved. In the steel industry as a whole the stocks of steel at mill are not only increasing, but are increasing at a more rapid rate than a month ago.

The further curtailment in car supplies is attributed to service order No. 7 of the Interstate Commerce Commission, giving preference in car supplies to coal mines. The original order was dated June 21, and it has since been renewed for an additional thirty days, or to Aug. 19. Last week there was some expectation of relief to the furnaces and mills by an interpretation issued, that the order is not to include, as coal cars, flat bottom gondola cars under 30 in. high, inside measurement. Previously most of the roads had been considering as coal cars any such cars over 30 in. in height. As an offset to the results of the new interpretation, however, has come strict enforcement of the point that coal cars may be loaded only in the direction of the coal. It seems there had been considerable evasion, or loose interpretation, of this point, but with the strict interpretation very few cars indeed will come under the permission.

The chief hope of the iron and steel trade in the matter of car supplies now is that the coal mines will soon be well enough supplied with cars that there will be a surplus for other uses. It is recognized that it will not be necessary to furnish the coal mines with 100 per cent of their theoretical requirements, for it is reasonably clear that with a considerably smaller supply than that one of these so-called "labor shortages" will develop, whereby additional cars could not be used. The shortage would not be in the number of men, but in the time put in, the experience of the river mines showing that the men are not willing to work day after day the full eight hours.

CURTAILMENTS

Thus far there has been practically no curtailment of steel production by reason of inability to ship, although of course there has been curtailment on account of fuel, chiefly coke, not being in abundance. Since the first of the month there has been more or less curtailment of finishing operations, by mills leaving more steel in semi-finished form. If, however, definite relief from present shipping conditions does not come within thirty days, or possibly sixty days at the very outside, it will be necessary for steel production itself to be curtailed. Possibly it would have been prudent to begin curtailing steel production before this. The finishing departments can stand only a

moderate overload, and to accumulate large quantities of unfinished or semi-finished steel would mean that the finishing departments would require a very long time to work off the surplus, providing of course they had to take care of current steel production at the same time.

The further difficulty is now becoming rather pressing, that finished steel rolled to customers' specifications may prove quite unacceptable months hence, it being clear that with the greatest improvement in transportation that can be hoped for it will be a long time before the last of the mill accumulations disappears. Accordingly many of the mills are now following a new policy in shipping, and are using such cars as are available for moving material that is particularly special in character, as for instance from being cut to length, and the mills are taking such material either from stock or from current rolling, as occasion presents itself. The object is to leave the mill, to such an extent as is possible, only with stock sizes on hand.

CONSTRUCTION WORK LIGHT

For several weeks past the mills have reported demand for plates and structural shapes as particularly light, this being quite in contrast with demand for merchant bars of the smaller sizes, this demand being quite heavy.

Prices for steel products for prompt shipment show further weakening in spots, although for sheets there seems to be a somewhat stiffer market. Prices of the large independents, for moderately early but rather uncertain delivery, are at the level that has ruled for several months, while the Steel Corporation prices are of course unchanged. Independent prices may all recede to the Steel Corporation level, though this is far from certain, but no one seems to think that the Steel Corporation level can possibly be endangered even should there be a continuance of this dull market for several months.

The Chemical and Allied Industrial Markets Today and a Year Ago

New York, July 23, 1920.

Inasmuch as the quiet that has become almost customary in the chemical market still persists, this week's article will compare prices with those of a year ago, instead of repeating the commonplace "news" of the last few months. Among the heavy chemicals there are only two items of current interest: (1) sulphate of aluminum, and (2) citric and tartaric acids. Ordinarily, sulphate of aluminum (iron free) sells for 3@4c. per lb. in car lots; but small stocks and the almost impossibility of obtaining bauxite has boosted the price to 6c. The commercial sulphate has advanced to 4½c., as against a former price of 1½@3c. As for citric and tartaric acids, the sharp drops are the outcome of too many speculators in sugar. Tartaric has declined from 80@85c. to 70@72c.; citric from 80@100c. to 78c.

In the coal tars it is interesting to note that one concern sold 19,000 lb. of *paranitraniline* in a single day last week, whereas there had not been a sale made in the two weeks preceding. *Beta naphthol* (technical) sells for 80@95c., against 45@55c. a year ago, owing to increased demand and smaller production because of shortage of raw materials. Improved methods of manufacture have lowered the price of *phthalicanhydride* from \$1.75@2.15 to 60@70c. per lb. Coal-tar products that are active at the present time are shown in the following table in comparison with prices a week ago and a year ago.

	Current	Week Ago	Year Ago
Aniline oils, drums extra	\$0.33 @ \$0.34	\$0.34 @ \$0.36	\$0.25 @ \$0.30
Aniline salts	0.40 @ 0.42	0.41 @ 0.45	0.28 @ 0.33
Beta naphthol, tech.	0.80 @ 0.95	0.80 @ 0.88	0.45 @ 0.55
Metaphenylenediamine	1.25 @ 1.30	1.23 @ 1.30	1.20 @ 1.80
Paranitraniline	1.30 @ 1.40	1.40 @ 1.50	1.00 @ 1.20
Paraphenylenediamine	2.50 @ 2.65	2.50 @ 2.75	2.75 @ 4.00
Phthalicanhydride	0.60 @ 0.70	0.65 @ 0.75	1.75 @ 2.15

In the ensuing tabulations for waxes, rosins, rubber and fish oil, it will be found that prices are generally lower than a year ago.

The Chicago Market

Chicago, Ill., July 21, 1920.

With apathetic demand, scarcity of spot stocks and producers sold up for some time to come in the general chemical line, with the vegetable oil market absolutely dead and with transactions in naval stores still hampered by lack of shipping facilities, there is little of interest to report from the Chicago district. The exhaustion of spot stocks of general chemical lines has tended to eliminate the second-hand dealer and the speculator, and the fact that factories have their entire output under contract for some time to come will prevent the re-entry of that element into the market in the near future.

HEAVY CHEMICALS

In the face of reports of a weaker market in the East the alkalis have held their own locally, as supply is extremely limited. *Caustic soda*, both solid and granulated, is firm at 6@6½c. per lb., with handlers of spots turning away more business than they are accepting. Contracts are quoted around 5½c. *Soda ash*, as scarce as ever, is nominally quoted at \$3.50 per cwt. and at least one transaction involving fifty drums was carried through last week at \$3.75 per cwt. *Sul soda*, when obtainable, commands \$1.90 per cwt. for delivery from stock and no futures are offered lower than \$1.70. Demand is materially in excess of available supply. Nominal quotations on bleaching powder range from 6c. to 7c. per lb. with but few actual transactions reported.

Stiff prices rule on *arsenic*, oxide lumps (white) being held firmly at 16½@17½c. per lb., depending on quantity. The powdered sulphide (red) is quoted at around 20c., with no undue pressure of demand. *Barium chloride* continues to advance, nominal quotation on imported being \$185 to \$190 per ton. But few transactions are recorded and they probably passed at figures slightly lower than quotations. *Carbon tetrachloride* shows little change, spots going for 11½@12c. per lb. Producers maintain this price is too low and offer contracts no lower than 13c. *Sodium sulphate crystals* (Glauber's salts) are at a premium for spots, \$2.75 per cwt. being the prevailing price. Futures are offered at about a dollar lower.

Nothing can be added to the last report in regard to *alcohol*. Both *ethyl* and *methyl* are available in quantities much less than normal demand and are finding a ready sale at the prevailing high prices. *Denatured*, under extraordinary demand, is up to \$1.10 a gal. Buying of *formaldehyde* seems restricted by high prices, and a reduction of 2c. in the prevailing price, to 53c. a lb., has failed to arouse any great interest. *Glycerine*, c.p., at 29c., remains in slack demand.

Acid business remains quiet, consumers being content to proceed on a hand-to-mouth basis. Offers of spot stocks at seemingly attractive prices find no active demand. Producers are rapidly catching up in deliveries on contract and spot supplies are ample. *Acetic*, 28 per cent commercial, is quoted at \$3.87½ per cwt. on contract. Holders of stocks of *carbolic* are finding but small demand at the offered price of 12c. per lb. *Muriatic* (hydrochloric) is not available in as great quantity as the others and but little is changing hands at \$3@3.15 per cwt. A wide range in offerings and slight demand are noted in *nitric*, 42 deg. being quoted at 7½@8c. per lb. *Sulphuric acid* is available for prompt delivery at \$23 per ton for 66 deg. in tanks.

VEGETABLE OILS

Development of the fact that practically unlimited supplies of flaxseed are in sight has brought *linseed oil* down to the lowest point for some time, with but little interest shown by either buyer or seller. Quotations for immediate delivery, f.o.b. Chicago, are: for tank car lots, \$1.52 per gal.; for car lots in cooperage, \$1.59, and for barrels in less than car lots, \$1.62. Contracts for future delivery are offered at 1½c. less than above figures, but with the expectation of still lower figures, business is light. For *cottonseed oil* the demand is so slight as to be negligible. Prime summer yellow is offered at 12½c. and refined, deodorized, at 19c., f.o.b. Chicago. *Coconut oil* is likewise dull at 12½c. per lb. in sellers' tanks, f.o.b. Coast. Spots from local stock go at 15½@16c. Current shipments of *soya bean oil*, in sellers' tanks, f.o.b. Coast, are offered at 10½c., with next month's delivery quoted at ¼c. less. Little interest is shown in any of these offerings.

NAVAL STORES

Supplies are being received much more freely now, several cars of *turpentine* having arrived during the last few days. Demand is sufficient to absorb receipts, and to maintain a price of \$1.75 per gal. on barrels in carload lots, 5c. less in drums. Requirements of *pine oil* are still in excess of supply and the price is firm at \$1.90 per gal. on both pure and destructively distilled. The shortage in the items was so great during the spring that it will take considerable time to get supply back to normal. Receipts of *rosin* are approaching normal, \$15.80@15.90 being today's ruling quotation on E, F and G grades.

The St. Louis Market

St. Louis, Mo., July 19, 1920.

The St. Louis chemical market continues quiet and prices for the most part are firm. Many of the larger buyers are contracting for their present needs only and manufacturers are loath to take on large contracts for future delivery on account of the present labor conditions and the raw material situation. The transportation situation continues to show improvement, although car movements continue to be slow. The supply of most chemicals is now ample to meet present demands and little change in prices is to be expected in the near future.

The demand for *sulphuric acid* continues good and prices show a small increase. The 60 deg. grade is quoted at \$15 per ton, an advance of \$1 per ton over two weeks ago. The 66 deg. is quoted at \$24 per ton, as against \$22 per ton two weeks ago. *Oleum* remains unchanged at \$27.50 per ton. Prices are based on carload lots.

The market for *muriatic acid* is quiet and prices are unchanged at \$25 per ton in carload lots and 2@2.25c. per lb. in carboys for the 18 deg. grade. The recent shortage of *sodium bisulphate* has been relieved. Price remains unchanged at \$6 per ton in carload lots.

Nitric acid is unchanged and quoted in carload lots at \$7 per cwt. for 36 deg., \$8 for 38 deg., \$9 for the 40 deg. and \$10 for the 42 deg. Standard *mixed acid* consisting of 36 deg. nitric and 61 deg. sulphuric acid is quoted at 11.5c. per lb. per degree of nitric and 1.5c. per lb. per degree of sulphuric acid. *Zinc chloride*, of 50 per cent solution, is unchanged at \$3.50 to \$3.75 per cwt. The supply of *phenol* is plentiful and prices are unchanged at 12c. per lb. in lots of fifteen tons or more.

Ethyl pure (acetic ether 98% to 100%).....	lb.		.57 - .65
Formaldehyde, 40 per cent (nominal).....	gal.		5.25 - 6.00
Fuel oil, ref.....	gal.		
Fuel oil, crude (nominal).....	gal.		
Glauber's salt (see sodium sulphate).....	lb.		
Glycerine.....	lb.	4.30 - 4.35	4.40 - 4.45
Iodine, resublimed.....	lb.		.03 - .20
Iron oxide, red.....	lb.		2.75 - 3.50
Iron sulphate (copperas).....	cwt.		
Lead acetate, normal.....	lb.	.11 - .12	.13 - .16
Lead arsenate (paste).....	lb.		.90 - 1.00
Lead nitrate, crystals.....	lb.	.14 - .15	.15½ - .16
Litharge.....	lb.		1.50 -
Lithium carbonate.....	lb.	.12 - .14	.15 - .16
Magnesium carbonate, technical.....	100 lb.	3.00 - 3.55	4.00 - 4.50
Magnesium sulphate, U. S. P.....	100 lb.		3.25 - 3.60
Magnesium sulphate, commercial.....	100 lb.		.14 - .16
Nickel salt, double.....	lb.		.13 - .14
Nickel salt, single.....	lb.		
Phosgene (see carbonyl chloride).....	lb.	.50 - .55	.60 - .65
Phosphorus, red.....	lb.		.35 - .37
Phosphorus, yellow.....	lb.		.57 - .60
Potassium bichromate.....	lb.		

	Carlots	Less Carlots
Potassium bitartrate (cream of Tartar).....	lb. \$0.52 - \$0.56	\$0.57 - \$0.58
Potassium bromide, granular.....	lb. .90 - .95	.90 - .95
Potassium carbonate, U. S. P.....	lb. .20 - .25	.47 - .50
Potassium carbonate, crude.....	lb. .15 - .17	.25 - .28
Potassium chlorate, crystals.....	lb. .30 - .33	.18 - .20
Potassium hydroxide (caustic potash).....	lb. .30 - .33	.35 - .38
Potassium iodide.....	lb. .15 - .17	3.35 - 3.41
Potassium nitrate.....	lb. .75 - .80	.12 - .21
Potassium permanganate.....	lb. .90 - 1.00	.83 - .93
Potassium prussiate, red.....	lb. .32 - .36	1.05 - .
Potassium prussiate, yellow.....	ton \$225.00 - 240.00	.35 - .40
Potassium sulphate (powdered).....	ton \$225.00 - 240.00	.40 - .
Rochelle salts (see sodium potassium tartrate).....		
Salammoniac (see ammonium chloride).....		
Salt soda (see sodium carbonate).....		
Salt cake.....	ton 40.00 - 50.00	
Silver cyanide (nominal).....	os. 1.25 - .	
Silver nitrate (nominal).....	os. .43 - .70	
Soda ash, light.....	100 lb. 3.50 - 3.55	3.50 - 3.55
Soda ash, dense.....	100 lb. .081 - .09	.075 - .12
Sodium acetate.....	100 lb. 2.60 - 2.75	3.00 - 3.50
Sodium bicarbonate.....	100 lb. .24 - .27	.28 - .29
Sodium bichromate.....	ton 7.00 - 7.50	8.00 - 10.00
Sodium bisulphate (nitre cake).....	lb. .081 - .10	.09 - .12
Sodium bisulphate Powdered, U. S. P.....	lb. .09 - .10	.11 - .12
Sodium borate (borax).....	100 lb. 1.50 - 1.80	1.80 - 2.00
Sodium carbonate (sal soda).....	100 lb. .11 - .12	.12 - .13
Sodium chloride.....	100 lb. .25 - .30	.32 - .35
Sodium cyanide, 96-98 per cent.....	100 lb. .18 - .	.19 - .20
Sodium fluoride.....	100 lb. .650 - 7.50	.03 - .04
Sodium hydroxide (caustic soda).....	100 lb. 2.50 - .	3.25 - .
Sodium hyposulphite.....	100 lb. 3.00 - 3.25	3.75 - 4.00
Sodium molybdate.....	100 lb. .16 - .18	.19 - .20
Sodium nitrate.....	100 lb. .32 - .35	.45 - .40
Sodium nitrite.....	100 lb. .031 - .04	.04 - .05
Sodium peroxide, powdered.....	100 lb. .23 - .27	.31 - .32
Sodium phosphate, dibasic.....	100 lb. .011 - .011	.02 - .02
Sodium potassium tartrate (Rochelle salts).....	100 lb. .011 - .011	.02 - .02
Sodium prussiate, yellow.....	100 lb. .011 - .011	.02 - .02
Sodium silicate, solution (40 deg).....	100 lb. .011 - .011	.02 - .02
Sodium silicate, solution (60 deg).....	100 lb. .011 - .011	.02 - .02
Sodium sulphate, crystals (Glauber's salt) ext.....	100 lb. 1.60 - 1.70	1.75 - 2.50
Sodium sulphide, crystal, 60-62 per cent (cone).....	100 lb. .09 - .10	.10 - .11
Sodium sulphite, crystals.....	100 lb. .14 - .15	.15 - .17
Strontium nitrate, powdered.....	100 lb. .17 - .18	.19 - .20
Sulphur chloride red.....	100 lb. .08 - .09	.10 - .10
Sulphur, crude.....	ton 25.00 - 30.00	.10 - .12
Sulphur dioxide, liquid, cylinders.....	100 lb. .09 - .	.30 - 4.35
Sulphur (sublimed), flour.....	100 lb. .30 - .35	3.40 - 3.90
Sulphur, roll (brimstone).....	100 lb. .42 - .44	.45 - .46
Tin chloride (stannous).....	100 lb. .16 - .18	.19 - .20
Tin oxide.....	100 lb. .13 - .13	.13 - .17
Zinc carbonate, precipitate.....	100 lb. .45 - .49	.50 - .60
Zinc chloride, gran.....	100 lb. .11 - .12	.12 - .13
Zinc cyanide.....	100 lb. .17 - .25	.25 - .25
Zinc dust.....	100 lb. .01 - .03	.04 - .06
Zinc oxide, U. S. P.....	100 lb. .01 - .03	.04 - .06
Zinc sulphate.....	100 lb. .01 - .03	.04 - .06

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude.....	lb. \$1.40 - \$1.50
Alpha naphthol, refined.....	lb. 1.10 - 1.70
Alpha naphthylamine.....	lb. .53 - .55
Aniline oil, drums extra.....	lb. .33 - .34
Aniline salts.....	lb. .40 - .42
Anthracene, 80% in drums (100 lb.).....	lb. .90 - 1.00
Benzaldehyde (f.f.o.).....	lb. 2.00 - 2.10
Benzidine, base.....	lb. 1.35 - 1.40
Benzidine, sulphate.....	lb. 1.15 - 1.25
Benzoic acid, U. S. P.....	lb. .91 - 1.00
Benzonitrile, U. S. P.....	lb. .83 - .90
Benzol, pure, water-white, in drums (100 lb.).....	gal. .35 - .40
Benzol, 90%, in drums (100 lb.).....	gal. .31 - .38
Benzyl chloride, 95-97%, refined.....	lb. .33 - .41
Benzyl chloride, tech.....	lb. .25 - .35
Beta naphthol benzoate (nominal).....	lb. 3.50 - 4.00
Beta naphthol, sublimed (nominal).....	lb. .85 - .95
Beta naphthol, tech (nominal).....	lb. 2.25 - 2.40
Beta naphthylamine, sublimed.....	lb. .18 - .17
Cresol, U. S. P., in drums (100 lb.).....	lb. .21 - .25
Ortho-cresol, in drums (100 lb.).....	gal. 1.15 - 1.15
Creosote acid, 97-99%, straw color, in drums.....	gal. 1.15 - 1.05
Creosote acid, 95-97%, dark, in drums.....	gal. .75 - .75
Creosote acid, 50%, first quality, drums.....	lb. .11 - .10
Dichlorobenzol.....	lb. 1.50 - 1.60
Dimethylaniline.....	lb. 1.35 - 1.45
Dimethylbenzol.....	lb. .30 - .37
Dinitrobenzol.....	lb. .32 - .35
Dinitrochlorbenzol.....	lb. .45 - .55
Dinitronaphthalene.....	lb. .40 - .45
Dinitrophenol.....	lb. .40 - .45
Dinitrotoluenol.....	lb. .40 - .45
Dip oil, 25%, tar acids, car lots, in drums.....	gal. .78 - .80
Diphenylamine (nominal).....	lb. .80 - .85
H-acid (nominal).....	lb. 2.25 - 2.50
Metaphenyl-nediamine.....	lb. 1.25 - 1.31
Monochlorobenzol.....	lb. .18 - .20
Monochloroaniline.....	lb. 2.00 - 2.40
Naphthalene crushed, in bbls. (250 lb.).....	lb. .19 - .19
Naphthalene, flake.....	lb. .75 - .85
Naphthalene, balls.....	lb. .14 - .19
Naphtholonic acid, crude.....	lb. .40 - .50
Nitrobenzol.....	lb. .18 - .25
Nitro-naphthalene.....	lb. 3.25 - 4.25
Nitro-toluenol.....	lb. .15 - .20
Ortho-amidophenol.....	lb. .80 - 1.25
Ortho-dichlor-benzol.....	lb. .25 - .40
Ortho-nitro-phenol.....	lb. .35 - .45
Ortho-nitro-toluenol.....	lb. 2.50 - 3.00
Ortho-toluidine.....	lb. 2.50 - 3.00
Para-amidophenol, base.....	lb. .08 - .12
Para-amidophenol, HCl.....	lb. 1.30 - 1.40
Para-dichlor-benzol.....	lb. .130 - .140
Paranitroaniline.....	lb. .130 - .140

Para-nitro-toluenol.....	lb. \$0.135 - \$0.150
Paraphenylenediamine.....	lb. 2.50 - 2.65
Paratoluidine.....	lb. 2.00 - 2.30
Phthalic anhydride.....	lb. .60 - .70
Phenol, U. S. P., drums (dest.), (240 lb.).....	lb. .12 - .20
Pyridin.....	gal. 2.00 - 3.50
Resorcin, technical.....	lb. 4.25 - 4.50
Resorcin, pure.....	lb. 6.25 - 6.75
Salicylic acid, tech., in bbls. (110 lb.).....	lb. .50 - .52
Salicylic acid, U. S. P.....	lb. .50 - .60
Salol.....	lb. .90 - 1.00
Solvent naphtha, water-white, in drums, 100 gal.....	gal. .33 - .35
Solvent naphtha, crude, heavy, in drums, 100 gal.....	gal. .23 - .26
Sulphanilic acid, crude.....	lb. .32 - .35
Toluidine.....	lb. 1.70 - 2.50
Toluidine, mixed.....	lb. .45 - .55
Toluol, in tank cars.....	gal. .35 - .40
Toluol, in drums.....	gal. .38 - .40
Xylidine, drums, 100 gal.....	lb. .50 - .65
Xylol, pure, in drums.....	gal. .37 - .45
Xylol, pure, in tank cars.....	gal. .35 - .45
Xylol, commercial, in drums, 100 gal.....	gal. .37 - .45
Xylol, commercial, in tank cars.....	gal. .23 - .27

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark.....	lb. \$0.36 - \$0.39
Beeswax, refined, light.....	lb. .39 - .40
Beeswax, white pure.....	lb. .61 - .68
Carnauba, No. 1 (nominal).....	lb. 1.00 - 1.05
Carnauba, No. 2, regular (nominal).....	lb. .85 - .88
Carnauba, No. 3, North County.....	lb. .35 - .36
Japan.....	lb. .19 - .19
Mountain, crude.....	lb. .23 - .25
Paraffine waxes, crude match wax (white) 10-110 m.p.....	lb. .09 - .09
Paraffine waxes, crude, scale 124-126 m.p.....	lb. .10 - .10
Paraffine waxes, refined, 118-120 m.p.....	lb. .11 - .12
Paraffine waxes, refined, 125 m.p.....	lb. .12 - .12
Paraffine waxes, refined, 128-130 m.p.....	lb. .14 - .15
Paraffine waxes, refined, 133-135 m.p.....	lb. .16 - .17
Paraffine waxes, refined, 135-137 m.p.....	lb. .17 - .18
Stearic acid, single pressed.....	lb. .24 - .25
Stearic acid, double pressed.....	lb. .25 - .26
Stearic acid, triple pressed.....	lb. .27 - .28

NOTE—Paraffine waxes very scarce.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Line oil, steam dist., sp. gr. 0.930-0.940.....	gal. \$2.30
Pine oil, pure, dest. dist.....	gal. 1.80
Pine tar oil, ref., sp. gr. 1.025-1.035.....	gal. .48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.....	gal. .35
Pine tar oil, double ref., sp. gr. 0.965-0.990.....	gal. .85
Pine tar, ref., thin, sp. gr. 1.080-1.090.....	gal. .36
Turpentine, crude, sp. gr. 0.900-0.970.....	gal. 2.00
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990.....	gal. .35
Pine wood creosote, ref.....	gal. .52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Roasin B-D, bbl.....	240 lb. \$12.25 - \$16.25
Roasin E-I.....	240 lb. 16.00 - 16.75
Roasin K-N.....	280 lb. 17.00 - 17.20
Roasin W. G.-W. W.....	280 lb. 17.25 - 17.50
Wood rosin, bbl.....	280 lb. 15.00 - .
Spirits of turpentine.....	gal. 1.58 - .
Wood turpentine, steam dist.....	gal. . - .
Wood turpentine, dest. dist.....	gal. . - .
Pine tar pitch, bbl.....	200 lb. 8.50 - .
Tar, kiln burned, bbl. (500 lb.).....	bbl. 14.50 - 15.00
Hetort tar, bbl.....	500 lb. 15.00 - 15.50
Roasin oil, first run.....	gal. .70 - .
Roasin oil, second run.....	gal. .75 - .
Roasin oil, third run.....	gal. .92 - .

Solvents

73-76 deg., steel bbls. (85 lb.).....	gal. \$0.40
70-72 deg., steel bbls. (85 lb.).....	gal. .38
68-70 deg., steel bbls. (85 lb.).....	gal. .37
V. M. and P. naphtha, steel bbls. (85 lb.).....	gal. .29

Crude Rubber

1 run—Upriver fine.....	lb. \$0.32 - \$0.33
Upriver coarse.....	lb. .23 - .24
Upriver caucho ball.....	lb. .23 - .24
Plantation—First latex crepe.....	lb. .32 - .
Ribbed smoked sheets.....	lb. .31 - .
Brown crepe, thin, clean.....	lb. .30 - .
Amber crepe No. 1.....	lb. .30 - .

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.....	lb. \$0.17 - \$0.18
Castor oil, AA, in bbls.....	lb. .19 - .19
China wood oil, in bbls.....	lb. .18 - .19
Cocoonut oil, Ceylon grade, in bbls.....	lb. .16 - .17
Cocoonut oil, Cochinchina grade, in bbls (nominal).....	lb. .17 - .17
Cora oil, crude, in bbls.....	lb. .16 - .16
Cottonseed oil, crude (f.o.b. mill).....	lb. .10 - .11
Cottonseed oil, summer yellow.....	lb. .13 - .13
Cottonseed oil, winter yellow.....	lb. .19 - .19
Lined oil, raw, car lots (domestic).....	gal. 1.20 - .
Lined oil, raw, tank cars (domestic).....	gal. 1.30 - .
Lined oil, boiled, car lots (domestic).....	gal. 1.35 - .

Olive oil, commercial.....	gal.	5.00	—	3.10
Palm, Lagos.....	lb.	.101	—	—
Palm, bright red.....	lb.	.101	—	—
Palm, Niger.....	lb.	.11	—	.12
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.121	—	.121
Peanut oil, refined, in bbls.....	lb.	.17	—	.18
Rapeseed oil, refined in bbls.....	gal.	1.65	—	—
Rapeseed oil, blown, in bbls.....	gal.	1.70	—	—
Soya bean oil (Manchurian), in bbls N. Y.....	lb.	.14	—	.141
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.101	—	.11

FISH

Winter pressed Menhaden.....	gal.	\$0.90	—	\$1.05
Yellow bleached Menhaden.....	gal.	0.95	—	1.05
White bleached Menhaden.....	gal.	1.00	—	1.25
Blown Menhaden.....	gal.	1.00	—	1.20

Miscellaneous Materials

All f. o. b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.	net ton	\$22.00	—	\$25.00
Barytes, ground, off color, f.o.b. Kings Creek	net ton	18.00	—	20.00
Barytes, crude, 88% a. 94% ba., Kings Creek	net ton	8.00	—	10.00
Barytes, ground, white, f.o.b. Cartersville, Ga.	net ton	23.00	—	25.00
Barytes, ground, off-color, f.o.b. Cartersville	net ton	10.00	—	19.00
Barytes, crude, 88% a. 94% ba., Cartersville	net ton	12.00	—	—
Barytes, floated, f.o.b. St. Louis	net ton	25.50	—	28.00
Barytes, crude, min. 98% ba., Missouri	net ton	11.00	—	11.25
Blanc fixe, dry.....	lb.	.05	—	.06
Blanc fixe, pulp.....	net ton	60.00	—	80.00
Casein.....	lb.	.15	—	.18
Chalk, domestic, extra light.....	lb.	.05	—	.06
Chalk, domestic, light.....	lb.	.04	—	.05
Chalk, domestic, heavy.....	lb.	.04	—	.05
Chalk, English, extra light.....	lb.	.05	—	.07
Chalk, English, light.....	lb.	.05	—	.06
Chalk, English, dense.....	lb.	.04	—	.05
China clay, (Kaolin) crude, f.o.b. mines, Georgia	net ton	9.00	—	12.00
China clay (Kaolin) washed, f.o.b. Georgia	net ton	12.00	—	15.00
China clay (Kaolin) powdered, f.o.b. Georgia	net ton	13.00	—	22.00
China clay (Kaolin) crude f.o.b. Virginia points.	net ton	8.00	—	12.00
China clay (Kaolin) ground, f.o.b. Virginia points.	net ton	15.00	—	40.00
China clay (Kaolin), imported, lump.....	net ton	5.00	—	35.00
China clay (Kaolin), imported, powdered.....	net ton	5.00	—	60.00
Feldspar, crude, f.o.b. Maryland and North Carolina points.....	gross ton	7.50	—	8.00
Feldspar, crude, f.o.b. Maine	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina	net ton	17.00	—	20.00
Feldspar, ground, f.o.b. N. Y. State	net ton	17.00	—	20.00
Fuller's earth, granular, f.o.b. Fla.	net ton	25.00	—	—
Fuller's earth, powdered, f.o.b. Fla.	net ton	18.00	—	—
Fuller's earth, imported, powdered.....	net ton	35.00	—	40.00
Graphite (dust polish grade 30%) Ashland, Va.	lb.	—	—	.01
Graphite (dust facing grade 50%) Ashland, Va.	lb.	—	—	.02
Graphite, crucible, 80% carbon Ashland, Va.	lb.	—	—	.05
Graphite, crucible, 90% carbon Ashland, Va.	lb.	—	—	.10
Graphite, crucible, 85% carbon	lb.	—	—	.08
Graphite, crucible, 88% carbon	lb.	—	—	.09
Graphite, crucible, 90% carbon	lb.	—	—	.10
Pumice stone, imported, lump.....	lb.	.04	—	.50
Pumice stone, domestic, lump.....	lb.	.05	—	—
Pumice stone, ground.....	lb.	.04	—	.07
Quartz (acid tower) 6 ft to 10 ft, f.o.b. Baltimore	net ton	—	—	10.00
Quartz (acid tower) 1 ft to 2 ft, f.o.b. Baltimore	net ton	—	—	14.00
Quartz (acid tower) 2 ft to 3 ft, f.o.b. Baltimore	net ton	—	—	17.00
Quartz, lump, f.o.b. North Carolina	net ton	5.00	—	7.50
Shells, orange.....	lb.	1.35	—	—
Shells, orange supertine.....	lb.	1.45	—	—
Shells, A. C. garnet.....	lb.	1.05	—	1.15
Shells, T. N.....	lb.	1.20	—	1.30
Soapstone.....	ton	1.00	—	25.00
Talc, paper-making grades, f.o.b. Vermont.....	ton	9.50	—	14.00
Talc, roofing grades, f.o.b. Vermont.....	ton	8.00	—	9.00
Talc, rubber grades, f.o.b. Vermont.....	ton	9.00	—	15.00
Talc, powdered, Southern, f.o.b. cars.....	ton	12.00	—	15.00
Talc, imported.....	ton	60.00	—	70.00
Talc, California Talcum Powder grade.....	ton	20.00	—	35.00

Refractories

Chrome brick, f.o.b. Chester, Pa., carlots	net ton	90	—	100
Chrome brick, 9-in. size, and sizes, f.o.b. Baltimore	net ton	80	—	90
Fire clay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works	1,000	45	—	53
Fire clay brick, 1st quality, f.o.b. St. Louis	1,000	45	—	—
Fire clay brick, 1st quality, f.o.b. New Jersey	1,000	75	—	—
Fire clay brick, 2d quality, 9-in. shapes f.o.b. Pennsylvania, Ohio and Kentucky works	1,000	40	—	—
Magnesite brick, 9 in. straights, f.o.b. Baltimore	net ton	90	—	100
Magnesite brick, 9-in. sizes and shapes larger than 9-in.	net ton	90	—	100
Magnesite brick, f.o.b. Chester	1,000	55	—	—
Silica brick, 9-in. and 9 in. sizes, Chicago district.	1,000	51	—	55
Silica brick, f.o.b. Birmingham	1,000	51	—	55
Silica brick, f.o.b. Mt. Union, Pa.	1,000	50	—	55

Ferro-Alloys

All f.o.b. Works

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	\$200.00	—	\$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon, carlots.....	lb.	.17	—	.18
Ferro-chrome, per lb. of Cr. contained, 4-6% carbon, carlots.....	lb.	.19	—	.20
Ferro-manganese, 76-80% Mn.....	gross ton	190.00	—	225.00
Spiegelisen, 18-22% Mn.....	gross ton	75.00	—	—
Ferro-molybdenum, 50-60% Mo, per lb. of Mo.....	lb.	2.50	—	3.00
Ferro-silicon, 10-15%.....	gross ton	60.00	—	65.00

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

California

CLAREMONT—Pomona College is having plans prepared for the construction of a 2-story, 60x200-ft. chemical laboratory. Estimated cost, \$200,000. James P. Jamison, Security Bldg., St. Louis, Mo., archt. and engr.

Connecticut

BRIDGEPORT—The Amer. Tube & Stamping Co., 471 Hancock Ave., will build a 1-story, 55x60-ft. manufacturing plant on Stratford Ave. Estimated cost, \$14,000. Work will be done by day labor.

BRISTOL—The City School Comm. will receive bids until Aug. 3 for the construction of a 3-story high school at Dunbar Meadows. A chemical laboratory will be installed in same. Estimated cost, from \$750,000 to \$800,000. Wilson Potter, 22 East 17th St., New York City, archt.

NEW HAVEN—The Fritzell Brass Fdry. Co., 33 Chestnut St., will soon award the contract for the construction of a 1-story, 60x150-ft. factory. Estimated cost, \$40,000. Fletcher Thompson Inc., 1089 Broad St., archt. and engr. Noted May 19.

NEW HAVEN—The Natl. Folding Box & Paper Co., James St., plans to build additions to plant.

NEW HAVEN—The New Haven Pulp & Board Co. has awarded the contract for altering a factory to Levering & Garrigues, 552 West 23d St., New York City. Estimated cost, \$30,000.

ROCKVILLE—The J. J. Regan Mfg. Co., 74 West Main St., has awarded the contract for the construction of a 1-story, 21x70-ft. addition to finishing plant and a 1-story, 40x80-ft. dye house to J. H. Grozier Co., 721 Main St., Hartford. Estimated cost, \$16,000.

STAMFORD—The Petroleum Heat & Power Co., Selleck St., has awarded the contract for the construction of a 1-story foundry to H. Wales Lines Co., 134 State St., Meriden. Estimated cost, \$15,000.

WATERBURY—The Waterbury Farrel Fdry. & Machine Co., 425 Bank St., will build a 1-story, 45x180-ft. factory addition. Estimated cost, \$45,000. Work will be done by day labor.

District of Columbia

WASHINGTON—The General Purchasing Office of the Panama Canal will receive bids until Aug. 2 for furnishing 3,200 lb. of bone black, hydrocarbonated, in barrels of approximately 400 lb. each, to be manufactured from selected hard white bone, charred, ground to a uniform mesh and then charged with additional carbon extracted from a hydrocarbon oil; 100,000 lb. of calcium carbide, 1½ in. commercially pure; and 5,000 lb. of asbestos magnesite furnace cement.

Illinois

CHICAGO—The Abbott Laboratories, 4753 Ravenswood Ave., will build a chemical manufacturing plant, including ten 1-story buildings, at 4800 Ravenswood Ave. Estimated cost, \$225,000. Work will be done by day labor.

CHICAGO—The Amer. Car & Foundry Co., 3417 Paulina St., has purchased a site along Paulina St., near Blue Island Ave., and plans to build a plant on same. Estimated cost, \$2,000,000.

CHICAGO—A. Finkel & Sons Co., 1326 Cortland St., had plans prepared for the construction of a 1-story, 32x98-ft. heat treating plant. Estimated cost, \$20,000. E. M. Newman, 80 West Washington St., archt.

Indiana

CROWN POINT—The Bd. of County Comm. had plans prepared for the construction of a 2-story, 100x200-ft. hospital here. Chemical laboratory equipment will be

installed in same. Estimated cost, \$400,000. J. N. Coleman, Chicago, Ill., archt.

EAST CHICAGO—The Carroll Castings Co. has purchased a site on the Indiana Harbor Belt R.R., Gibson St., and plans to construct a plant for the manufacture of small gray iron castings on same. Equipment will be installed in same.

INDIANAPOLIS—The General Amer. Tank Car Corp., Euclid Ave. and 145th St., East Chicago, plans to build a large addition to its brass foundry and is in the market for equipment for same.

INDIANAPOLIS—The Pioneer Brass Wks., 424 South Pennsylvania St., has awarded the contract for the construction of a 1-story, 200x300-ft. factory on 23rd St. and the Lake Erie Western R.R. to John G. Karstedt Constr. Co., 129 Lemcke Bldg. Estimated cost, \$200,000.

INDIANAPOLIS—The Pioneer Brass Wks., 424 South Pennsylvania St., plans to install new foundries and equipment in the proposed plant here.

INDIANAPOLIS—The United States Fiber Box Co., Martindale and Roosevelt Aves., is having preliminary plans prepared for the construction of a 4-story, 100x160-ft. factory on Martindale Ave. Estimated cost, \$125,000. Charles E. Bacon, 617 Merchants Bank Bldg., archt.

INDIANAPOLIS—The Universal Slag Brick & Tile Co., Gary, Ind., is in the market for \$50,000 worth of machinery for use in plant including all machinery used in making tile and brick.

WEST HAMMOND—The La Salle Iron Works, 2305 South Halsted St., Chicago, has awarded the contract for the construction of a steel plant including seven 1-story buildings, to the Broline Nolan Co., 8 South Dearborn St., at \$650,000.

Iowa

CUSHING—A. H. Bullock, Secy. of the Bd. of Educ., has awarded the contract for the construction of a 3-story, 59x111-ft. school, to W. F. Kucharo & Co., 622 Hubbell Bldg., Des Moines, at \$111,414. Chemical laboratories will be installed in same.

LARABEE—H. Montgomery, Secy. has awarded the contract for the construction of a 3-story, 82x139-ft. school, to W. F. Kucharo & Co., 622 Hubbell Bldg., Des Moines, at \$124,500. A chemical laboratory will be installed in same.

MORNING SUN—The Bd. Educ. has awarded the contract for the construction of a 2-story, 56x130-ft. school, to the Western Constr. Co., Earlham, Ia., at \$142,400. Chemical laboratories will be installed in same. Noted May 12.

MUSCATINE—The Muscatine Packing Co. has awarded the contract for the construction of a 4-story, 54x64-ft. fertilizer building in connection with the proposed packing plant, to the Federation Constr. Co., 532 Davidson Bldg., Sioux City. Estimated cost, \$1,000,000.

PACKWOOD—N. E. Oliver, Secy. of the Bd. Educ., has awarded the contract for the construction of a 2-story, 58x99-ft. school, to W. F. Kucharo & Co., 622 Hubbell Bldg., Des Moines, at \$92,980. Chemical laboratories will be installed in same. Noted May 12.

POCAHONTAS—W. J. Gilchrist, Pres. of the School Bd., has awarded the contract for the construction of a 2-story, 56x110-ft. school, to C. E. Larson, Fort Dodge, at \$118,000. Chemical laboratories will be installed in same. Noted June 16.

Louisiana

NEW ORLEANS—The Prest-O-Lite Co., 30 East 42nd St., New York City, has purchased a site on Anthony and St. Louis Sts., for the construction of a 2-story acetylene plant.

Massachusetts

CHELSEA—The Walker Bros. Dyeing & Bleaching Co., Clinton St., plans to rebuild bleaching recently destroyed by fire. Estimated cost, \$50,000.

FALL RIVER—The New England Oil Co. will build a 1-story, 17x25-ft. oil receiver house, 32x74-ft. oil condensers and 45x181-ft. oil stills, etc., along the Taunton River here. Estimated cost, \$100,000. Work will be done by day labor.

HOLYOKE—The New England Tire & Rubber Co., 285 High St., has awarded the contract for the construction of a 3-story, 110x210-ft. factory on Main St., to the Casper Ranger Constr. Co., 20 Bond St. Estimated cost, \$350,000.

SPRINGFIELD—The Buckley Fdry Co., 13½ Cypress St., has awarded the contract for the construction of a 1-story, 85x100-ft. foundry on Roseland St., to J. G. Roy & Sons Co., 21 Silver St., at \$8,600.

Michigan

LAY CITY—The city is having preliminary plans prepared for the construction of a filtration plant, etc., in connection with the proposed waterworks improvements. Estimated cost, \$2,000,000. Frazier-Elms-Shael Co., 1223 Illuminating Bldg., Cleveland, O., engra.

DETROIT—The Michigan Grey Iron Casting Co., Harbaugh Ave., plans to build a 1-story foundry addition on Harbaugh Ave. and the Wabash Ry. Estimated cost, \$10,000. E. J. Winter, 2331 Dime Bank Bldg., archt.

Minnesota

COLUMBIA—The Indian School Dist. 2, Itasca Co., has awarded the contract for the construction of a 2-story, 176x208-ft. high school, to Evenson & Utterberg, 552 Builders' Exch., Minneapolis, at \$455,000. A chemical laboratory will be installed in same. Noted June 9.

MINNEAPOLIS—The State Bd. of Control, Capitol St. Paul, will soon award the contract for the construction of a 3-story, 80x110-ft. chemistry building on the State University campus here. Estimated cost, \$200,000. C. H. Johnston, 716 Capital Bank Bldg., St. Paul, archt.

Missouri

ST. LOUIS—The St. Louis Surfactant Paint Co., 5132 Hazel Ave., has awarded the contract for a 2-story, 40x64-ft. manufacturing building on Hazel Ave., to George I. Cousins & Co., Chemical Bldg. Estimated cost, \$30,000.

New York

MARCY—The State Hospital Comm., Capitol, Albany, will receive bids until Aug. 25 for the construction of a mechanical gravity filtration plant, etc., for the Ulster State Hospital here. Noted July 7.

TONAWANDA—The city has awarded the contract for the construction of a filtration plant, to the Roberts Filtration Co., Philadelphia, Pa., at \$200,000. Noted April 14.

North Dakota

GRAND FORKS—The Industrial Comm. of North Dakota has awarded the contract for the construction of a reservoir and filter plant, etc., to the Eagles Constr. Co., Minneapolis. Noted May 19.

Ohio

CANTON—The Canton Drop Forge Co., 300-400 Odd Row Pl., S.E., plans to build a 1-story, 95x100-ft. factory on Willet Ave., S.E. Estimated cost, \$45,000. C. E. Firestone, Renkert Bldg., archt.

GLENMONT—The Bd. Educ. has awarded the contract for the construction of a grade and high school here, to the State Constr. Co., 11 State St., Columbus. A chemical laboratory will be installed in same. Estimated cost, \$80,000.

IRONTON—The Bd. Educ. is having plans prepared for the construction of a high school here. A chemical laboratory will be installed in same. Estimated cost, \$600,000. F. L. Packard, Hayden Bldg., 16 East Broad St., Columbus, archt.

KENTON—The Bd. Educ. plans to construct a high school here. A chemical laboratory will probably be installed in same. Richards, McArt & Bulford, 1504 East Broad St., Columbus, archts.

MIAMISBURG—The Bd. Educ. is having plans prepared for the construction of a 2-story, 120x140-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$200,000. F. L. Packard, New Hayden Bldg., archt.

MIDDLETOWN—The Advance Bag Co., 155 North B'way, has awarded the contract for the construction of a 3-story, 65x300-ft. paper factory, to J. R. Stevens, Old Fellows Temple, Cincinnati, at \$150,000.

SOUTH EUCLID—The Bd. Educ. will soon award the contract for the installation of septic and filter tanks in the streets adjoining the Victory Park School. Estimated cost, \$25,000. W. H. Nicholas, 1900 Euclid Ave., Cleveland, engr.

WARREN—The Bd. Educ., c/o J. Buckwaller, received bids for the construction of a 2-story, 110x182-ft. school addition to the West Technical High School, from the Shustrump Co., Youngstown, \$329,869; for a 2-story, 125x150-ft. school addition to the East Technical High School, \$322,212. Laboratory equipment will be installed.

Pennsylvania

CEDAR GROVE (Philadelphia P. O.)—J. F. Stokes, 17th and Cambria Sts., has awarded the contract for the construction of a 1-story plant for the manufacture of chemical machinery, to John N. Gill, Otis Bldg., Philadelphia.

DERRY—The Pittsburgh High Voltage Insulator Co. plans to improve and enlarge its plant here. Plans include a 101x244-ft. building which will be equipped with new clay mixing machinery. Estimated cost, \$150,000.

SCRANTON—The Bour Refractories Co., Laurel Line and Front St., plans to build a 3-story, 90x200 ft. refractory addition on Stafford Ave. Estimated cost, \$300,000.

Rhode Island

PROVIDENCE—The Franklin Process Co., 29 Promenade St., will soon award the contract for the construction of a 2-story, 110x175-ft. dye house. Estimated cost, \$150,000. Lockwood, Greene & Co., 60 Federal St., Boston, archts. and engr.

Tennessee

MEMPHIS—The Fly Shot Co., Nashville, Ga., has purchased a site on Dowd Ave. and 4th St., and plans to construct a 2-story, 50x150-ft. insecticide factory on same. Estimated cost, about \$100,000.

Virginia

AUSTINVILLE—The Bertha Mineral Co. will build a mining, milling and smelting plant. Work will be done by day labor.

NORFOLK—The city is having plans prepared for the construction of a water plant. A filtration system will be installed in same. Estimated cost, \$4,000,000. W. H. Taylor, Dir. of Pub. Wks.

ROANOKE—The Greenstone Products Co. Inc. plans to build a slate granite plant to have a daily capacity of 1,000 tons. L. P. Costy, secy. and treas.

West Virginia

SHINNISTON CITY—The city plans to build a 100,000-gal. filtration plant. Estimated cost, \$75,000.

Wisconsin

MERTON—The Merton Dairy Products Co. is having plans prepared for the construction of a 1-story, 45x70-ft. addition. Estimated cost, \$35,000. Laboratory equipment will be installed in same. M. Tullgren & Sons, 125 E. Water St., Milwaukee, archt.

MILWAUKEE—The Badger Brass Co., 243 Lake St., is in the market for brass foundry equipment.

MILWAUKEE—Milwaukee County plans to build an 8- and 6-story hospital on Grand Ave. Chemical laboratories will be installed in same. Estimated cost, \$2,000,000. Van Ryn & DeGelleke, Caswell Bldg., archts.

MILWAUKEE—St. Mary's Hospital, 448 Lake Drive, plans to build an addition to a hospital. A chemical laboratory will be installed in same. Estimated cost, \$200,000.

NEENAH—The Theda Clark Hospital has awarded the contract for the construction of a 2-story, 40x100-ft. hospital addition, to C. R. Meyer & Son, 50 State St., Oshkosh. A chemical laboratory will be installed in same. Estimated cost, \$75,000.

WAUKESHA—The Waukesha Casting Co. has awarded the steel contract for a 120x130-ft. foundry, to the Federal Bridge Co., at \$50,000. Noted July 14.

Ontario

FORT WILLIAM—The Fort William Pulp & Paper Co. has awarded the contract for the construction of a 2-story, 400x600-ft. pulp and paper mill at the mouth of the Mission River, to the Barnett McQueen Co., at \$1,800,000. Noted July 21.

TORONTO—The Grinnell Co. Ltd. has awarded the contract for the construction of a 1-story, 100x150-ft. foundry building to the Anglin Norcross Co. Ltd.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its 1920 meeting Dec. 27, 1920, to Jan. 1, 1921, at Chicago, Illinois.

AMERICAN CERAMIC SOCIETY will hold its summer meeting at the La Salle Hotel in Chicago, Aug. 16, 17 and 18.

AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Chicago, Sept. 7 to 10 inclusive.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in the Hotel Statler, Cleveland, Ohio, Sept. 30, Oct. 1 and 2.

AMERICAN FOUNDRYMEN'S ASSOCIATION will meet in Columbus, Ohio, Oct. 4 to 8 inclusive.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its one hundred and twenty-second meeting Aug. 20 to Sept. 3, at Lake Superior.

AMERICAN MINING CONGRESS will hold its next convention in Denver Nov. 15.

AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

AMERICAN STEEL TREATERS' SOCIETY, Chicago, will hold its second annual convention and exhibit, combined with the convention of the Steel Treating Research Society of Detroit, Mich., in the Coliseum Museum, Philadelphia, Pa., Sept. 14 to 18 inclusive.

ASSOCIATION OF IRON AND STEEL ELECTRICAL ENGINEERS will hold its 14th annual convention at the Hotel Pennsylvania, New York City, Sept. 20 to 24, 1920.

ENGINEERING COUNCIL will hold its next meeting in Chicago, Thursday, Oct. 21, 1920.

INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

IRON AND STEEL INSTITUTE (British) will hold its autumn meeting at Cardiff by invitation of the Ironmasters and Steel Manufacturers of South Wales and Monmouthshire. The date of the meeting will be Tuesday, Sept. 21, for the assembling of the members at Cardiff, and the formal proceedings will open on the morning of Wednesday, Sept. 22.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SIXTH) will be held in the Grand Central Palace, New York City, Sept. 20 to 25.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall national convention at Carnegie Music Hall, Pittsburgh, Pa., Nov. 10, 11 and 12, 1920.

TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its fall meeting at Saratoga Springs, N. Y., Sept. 1, 2 and 3.

Industrial Notes

DREW, STRONG & TOWNSEND, patent attorneys, announce the entry of Capt. W. A. Loftus and Thomas Castberg, J. A. Abbott and J. H. Herring into the firm, which will be known as Dewey, Strong, Townsend & Loftus. Mr. Abbott will specialize in chemical and electrical patent matters and Mr. Castberg will devote his attention to engineering and industrial patent cases. The offices will remain in the Crocker Bldg., San Francisco.

THE MOLYBDENUM CORP. OF AMERICA, Empire Bldg., Pittsburgh, Pa., having the same executive and operative personnel as that of the Electric Reduction Co., announces that it has acquired as of July 1, 1920, the plant, equipment and operations of the Electric Reduction Co. at Washington, Pa., together with extensive molybdenum mines in New Mexico. This company will continue to furnish ferrotungsten, ferro-molybdenum and other high grade ferro-alloys, metals and chemical products as heretofore furnished by the Electric Reduction Co., with no change in policy whatever. Having now direct control from the crude ore to the finished material the Molybdenum Corp. of America is in position to render exceptional service in supplying molybdenum products.

THE GLIDDEN CO., Cleveland, O., uses in its sixteen paint and varnish plants a tremendous quantity of lithopone. With a view to insuring a uniform supply of this important commodity it has acquired the St. Helena lithopone plant of the Chemical Pigments Corp. The capacity of the plant will be increased to meet the needs of the Glidden Co. The present staff will be maintained and augmented. The business will be operated under the name of the Glidden Co. Lithopone Department.

THE AMERICAN METALLURGICAL CORP., Philadelphia, which was the controlling factor of the Philadelphia Electric Steel Corp., announces the reorganization of that company's affairs along the following lines: E. C. Hummel, who has been the electric steel foundry superintendent at the United Alloy Steel Corp., Canton, Ohio, has purchased a controlling interest and has re-incorporated the company, which will be known as the Philadelphia Electric Steel Castings Co. The new directors and officers of the corporation will be: E. C. Hummel, president and general manager; F. J. Ryan, vice-president and treasurer (Mr. Ryan is also president of the American Metallurgical Corp.); P. H. Schrenk, secretary (Mr. Schrenk is also the attorney for the American Metallurgical Corp.); C. T. Hess, director (Mr. Hess is vice-president of the E. P. Wilbur Trust Co., Bethlehem, Pa.); R. V. Mitchell, director (Mr. Mitchell is the manager and secretary of the United Securities Co., Canton, Ohio). The American Metallurgical Corp. retains a 40 per cent interest in the new corporation. Operation under the new management commenced on July 9 and it is the intention of the new controlling factors to enlarge the plant considerably as soon as production has been reached through the present equipment. The furnace capacity has already been doubled. The plant will manufacture high-grade steel castings in addition to special alloy heats, especially catering to instrument and automobile concerns. At the beginning the product will be entirely castings, but later the plant will be enlarged in order to take care of production of small blooms for forgings. This work will all be taken care of through high-speed tool steel.

THE INDIANA INDESTRUCTIBLE PAINT CO. has moved to a new location at 1247 Belmont Ave., Chicago. The new quarters consist of a four-story factory 50 x 125 ft.

Manufacturers' Catalogs

C. F. PEAKE CO., 813 North Franklin St., Chicago, Ill., has issued its new catalog No. F-20, called "Drafting Room Practice."

BRIQUS & TURVAS, INC., 1309 Westminister Bldg., Chicago, Ill., has issued a new publication entitled "Classified Scrap Iron." It is a very valuable little handbook for those who are interested in either the sale or purchase of scrap metal.

NORTON CO., Worcester, Mass., has issued three little booklets, entitled: "The Balancing of Grinding Wheels for Norton Precision Grinding Machines," "Norton Grinding Wheels on the Blanchard Surface Grinding Machines," and "Commercial Diamonds for Truing Grinding Wheels."

LEA-COURTNEY CO., Newark, N. J., has issued a little booklet on "Typical Examples of Lea-Courtney Centrifugal Pumping Machinery" known as Bulletin S-5, which illustrates and describes a few of its different types of centrifugal pumping machinery.

THE GRISCOM-RUSSELL CO., 90 West St., New York, has just received from the press Bull. No. 1010, on G-R Expansion Joint, Low Pressure.

THE ESTERLINE CO., Indianapolis, Ind., desires to announce Bull. No. 395, covering power factor recording instruments. In this bulletin are pointed out the evils of low power factor to the central station, the isolated plant and the power customer, as well as how to locate and eliminate the causes of low power factor. Copies can be secured upon request.

THE FULLER ENGINEERING CO., Allentown, Pa., is distributing Bull. No. 800, on Metallurgical Furnaces, Annealing and Heat-Treating. The furnaces illustrated and described are representative of the types this company build, including the use of pulverized coal, oil or gas as fuel.

BAUSCH & LOMB OPTICAL CO., Rochester, N. Y., calls attention to a new bulletin on Metallographic Equipment.

Reconstruction the Theme

For A. C. S. Chicago Meeting

INCREASED production through chemistry, and the part which the science can play in the reconstruction of our industries, is to be the theme of the Chicago meeting of the American Chemical Society in September. The topic is timely and should develop some valuable suggestions for those whose chemical control of manufacture has not yet reached the highest development. There is scarcely an industry of any magnitude in which chemistry does not play a part of greater or less importance. And those are few, no matter how highly developed, that cannot profit by looking ahead and giving thought to the improvements that will follow the adoption of better technology. In fact, a casual survey of the largest and most prosperous of our industries will reveal a lively appreciation of the value of chemistry and allied sciences.

If there is one lesson we can learn from our late enemy—who technically still occupies that unhappy position—it is the wisdom of co-ordinating the science of chemistry with the operations of industry. Notwithstanding popular impressions to the contrary, Germany is not noted for fundamental contributions to chemistry. Read the history of the science, and you will search almost in vain for the names of Germans who lifted chemistry out of the realm of crude speculation and placed it on a sound theoretical basis. English, French, Scandinavians were the pioneer thinkers. But none has been quite so industrious as the German in applying to manufacture the fundamental facts developed by others. This is one of the outstanding features in Germany's industrial growth; and if the noblest use has not always been made of it, other national traits must be called to account. Anyhow the lesson is there and may well be learned.

The forward-looking and progressive slogan adopted for the chemists at Chicago is in curious contrast to the reactionary tendencies evident in our political life. There is much talk in conventions and by candidates for high office of a return to pre-war conditions in methods of government and party control. Faith is expressed in the doctrines of the fathers; reliance is placed in tried methods; and confidence reposes not in a new day but in the old. Chemistry, on the other hand, has its face to the rising sun and places its hope in the new things it can do for sound reconstruction.

Incidentally, it is worth while noting the plans which the local committees of the American Chemical Society are making for the Chicago meeting. Profiting by past experience in other cities, they are showing commendable initiative in arranging for technical sessions and social functions under the most favorable conditions. The tentative plans published in our last issue are an earnest of what may be expected in September.

An Organization

Of Potential Influence

ENGINEERS often tell themselves, or are often told by non-technical admirers, that as a profession they are not exerting an influence upon human activity as wide as they deserve. Without wishing to set themselves up as persons who could do almost anything better than the fellow who is doing it, engineers can therefore be pardoned for hoping that the newly formed Federated American Engineering Societies can quickly bring the best trained talent to focus on a subject of economic importance and then present the decision with all the prestige and ability inherent in a united body of men of recognized intelligence. The public in general is impressed by the ability underlying the many engineering triumphs daily serving its comfort and convenience; it now remains to capitalize this prestige in a nation-wide organization.

However, these ideas are almost always nebulous, and the words which usually express them clothe glittering generalities. "What can a Federation of Engineering Societies do? Give me something specific" will be insisted by many of the more practical among us. Even when definite tasks are proposed many of them seem of very narrow gage.

ARTHUR P. DAVIS, the President of the American Society of Civil Engineers and Director of the U. S. Reclamation Service, has mentioned one instance drawn from recent history which may appeal to some as indicating the way in which a national engineering organization may really be most useful. That is to say, since the problems before that body are at present somewhat indefinite it would be well worth the effort of its creation and maintenance as a being of potentiality, capable of exerting large influence on short call.

Older engineers can remember the agitation in favor of the Nicaragua Canal—a diligent agitation carried on for many years by men of national prominence. Even after this Government was bound by treaty to construct the Panama Canal, bills favoring Nicaragua were year after year introduced into Congress, and pressed with all the devices of skilled lobbyists.

The matter finally came to a point where it was referred to three engineers for a technical opinion, Messrs. LUDLOW, NOBLE and ENDICOTT. The work they did in that connection will ever be known as a most honorable achievement. With an appropriation so insufficient that these men had to forego their compensation and still have but a fraction of the funds necessary for thorough investigation, they devoted themselves with sufficient energy and persistence to show that the Nicaraguan scheme was full of glaring blunders, that many proposals were clearly unworkable and that the plan had received millions for promotion to thousands for investigation.

These three men were strong and brave enough to set these facts before the American people. Their work was directly responsible for a second commission backed by an appropriation fifteen or twenty times as large as the original, which even yet was supplemented as entirely inadequate. Finally the Panama route was investigated in detail, and after all the influence that malice and malignity or honest and well-meaning opposition could bring to bear the American Government was saved from a blunder and failure at Nicaragua beside which the best French attempt at Panama would have been a pigmy.

LUDLOW, NOBLE and ENDICOTT did their work almost unassisted. Naturally, there were many supporters in the technical and daily press, and among the more responsible Congressmen and Government officials—without which, of course, they could not have gone very far. But how much better would it have been if the entire engineering profession had been behind them, with every resource of a complete organization! Under such circumstances they unquestionably could have accomplished the task which was finally done, although often perilously near failure, with half the effort, risk and self-denial.

Other tasks, more important and more insistent for correct performance, will arise from time to time before the American Engineer. He will do well to note how successful HERBERT HOOVER was when as food controller and relief administrator he was backed by a closely knit organization. What could have been done by even Mr. HOOVER without such support?

Science, Population

And Means of Subsistence

WHEN at the close of the eighteenth century the English economist THOMAS ROBERT MALTHUS wrote his Essay on Population he might have been justified in lamenting the misfortunes consequent on the tendency of population to increase faster than the means of subsistence, though at the present time it would seem preposterous to admit that population increases in a geometrical ratio while means of subsistence increases only in an arithmetical ratio. In his time little was known of the powers of chemistry, and the natural wealth of the populated areas, small as they were, was scarcely realized. The toilers of the soil prayed for rain and good crops instead of working out their own salvation by the application of scientific methods. Since that time necessity has been a great incentive toward balancing the increase of population with the food supply and other needed accessories, and has resulted in great strides in scientifically reclaiming waste areas, chemically stimulating returns from the soil, methodically working the natural raw products, and especially using the hitherto practically useless raw material supplies from different parts of the world. Relatively little progress has been made up to this time, but the little already accomplished has given excellent results, so that food production stoutly keeps pace with the increase of population.

How much more might be expected can be surmised from an analysis of the contribution of all branches of science and engineering to the welfare of humanity, and from a better knowledge of economic geography as typified by the phenomenally rapid progress of the United States since MALTHUS' time; nor is our country a unique exception. Following closely in the steps of

the guardian nation comes the community of the Philippine Islands, which up to a few decades ago was a territory practically unknown to the rest of the world. First-hand information about the current economic status of this region contributed by Dr. ALVIN J. COX, in our last issue, may be taken as typical of similar descriptions which might be made of the resources of other parts of the Australasian and African continents. It shows that the natural heritage of the human race, when used in accordance with scientific and engineering principles, is and will be amply sufficient at all times to meet the necessities and luxuries of life.

MALTHUS was right in his time, but he lacked light and vision.

Utilization of Oxygen in Non-Ferrous Metallurgy

AMONG the more important developments in non-ferrous metallurgy have been new methods or improvements in old methods of ore concentration. These have resulted in changes as to both type and design of metallurgical furnaces. Of importance also is the recovery of byproducts, hastened perhaps by the necessity of removing deleterious impurities from smelter gases as a result of smoke-damage suits but receiving additional impetus as the value of these byproducts has increased or as methods have been devised for their economical utilization. Many of the larger plants are now producing sulphuric acid, the Tacoma smelter is producing liquid sulphur dioxide, and there are several plants at which arsenic is recovered. A further step in advance may result from the use of oxygen to enrich the gases supplied to metallurgical furnaces—in other words, from the concentration of the gases as well as the ores.

The utilization of oxygen in this manner has been the dream of chemists and metallurgists. The late J. E. JOHNSON, JR., pointed out the advantages of oxygen-enriched gases in iron blast-furnace operation, predicting the necessity of its use as the grade of available ores decreased; and F. G. COTTRELL has frequently and forcibly called attention to the desirability and practicability of enriching gases with oxygen in the non-ferrous metallurgical furnaces. Some inconclusive experiments were carried out in Belgium before the war, which, with JOHNSON'S, are probably the only tests that have been conducted up to the present.

That the use of oxygen in metallurgical operations is receiving serious attention, on the part of some metallurgists at least, is evidenced by the patent recently granted to FREDERICK LAIST and FREDERICK F. FRICK of the Anaconda Copper Company's staff. At Anaconda a large quantity of sulphur dioxide is produced, all of which cannot be converted into sulphuric acid, as it is improbable that a market could be found for the product. On the other hand, there is a market for liquid sulphur dioxide and for sulphur. The dilute sulphur dioxide gases from ordinary furnace operations cannot easily be liquefied or converted into sulphur. If, however, the concentration of the sulphur dioxide of these gases can be increased, both of these operations are simplified and become economically possible. In order to obtain a gas containing a larger proportion of sulphur dioxide it is proposed to replace the air supplied to the furnaces by a mixture of oxygen and sulphur dioxide. The exit gases from a furnace would

consist principally of sulphur dioxide. A portion of this gas would be returned to the furnace and enriched with a regulated amount of oxygen in order to avoid the intense action of pure oxygen on the sulphide materials. The remainder of the exit gases can either be compressed for the production of liquid sulphur dioxide or be treated with carbonaceous material in a suitable apparatus for the production of sulphur.

It is true in this instance that oxygen is to be used to accomplish a particular result and that the advantages to be gained by its use in the operation of the furnace are in the nature of secondary consideration. Yet it is to be hoped that the experiment will be tried, as it would be conducted under favorable circumstances and if successful would hasten an important metallurgical development.

Utilizing Lower Grade Iron Ores

AS HAS been well known for a long time, the total quantity of iron-bearing material in the earth's crust is very large, the iron content of material that is moderately well known being probably dozens of times the amount of iron that has actually been produced in the world to date. About fifteen years and more ago much interest was exhibited in certain quarters over "the world's supplies of iron ores" and studies were made indicating that the supplies of "iron ore" were relatively limited, usually involving a life measured only by decades. Most of these studies were made from an objectionable viewpoint—that of regarding the iron ore of the future as definable by existing standards. In many cases what is the waste material of one time becomes the mineral of another. In the case of iron-bearing material this is particularly true. Indeed, on account of the low value and great weight involved, there have been contemporary cases of this sort. At no time in the past would the iron ore of Alabama be iron ore if found in Sweden. The Swedish industry, using first charcoal only and later charcoal and electricity, required a rich material, which it had or produced by concentration. The blast furnaces that used the early pickings from the Lake Superior region would not have regarded as ore the material that has since been utilized in hundreds of millions of tons from the Minette district of Europe.

What the studies referred to really indicated was that as time passed lower and lower grade material would have to be used as iron ore. Even though in iron ore explorations little attention has been paid to the iron-bearing material that was not classifiable at the time as iron ore, it has always been the case that the known material below the ore limit was many times greater than the known material then classed as ore.

The Lake Superior region now stands in the delicate position of having its future depend upon the processes men develop and apply for beneficiating iron ore. The present known reserves in the region meeting the present standard are sufficient for only from fifteen to thirty years, according to various estimates made, but iron and steel are likely to be made for an indefinite time in the future. The various districts will be in competition. If the Lake Superior region develops sufficiently cheap means for beneficiating its low-grade material, it will survive the competition with the ore of the South and other districts in the United States as well as the competition of the rich ores of various foreign countries. Utilization of one material or another

by blast furnaces, or whatever appliances are employed to make the merchantable product, will depend upon costs. The absolute cost will have nothing to do with the matter. Particularly on account of experiences of the past few years, it is plain that a difference of a few dollars a ton in the cost of steel means nothing as to regulating the quantity consumed, but even a very few dollars a ton is a great deal with iron ore.

Each district will have its own problems. There will be no solution open to all districts, to be utilized by each according to its degree of enterprise. In the case of Chilean and other far off but rich deposits, the chief matter will be one of cheap transport. With Lake Superior it will be a matter of cheap concentration, on the ground, since the ore must travel long distances and the methods of transportation cannot be very greatly improved upon. With Alabama it will be a matter of more economical methods of mining iron ore and producing coke, and so with all districts in the competition that is to come. Not so much the present geological conditions, but rather what men do, will determine the relative importance of the various iron ore districts a quarter century from now.

The Factors Influencing the Adhesive Properties of Glues

EVER since the time of PETER COOPER the question of grading glues has been an open one and free to individual opinion. The "Cooper Standards" have been used in commerce so long that they may be regarded as venerable and valuable antiques to be continued in use as long as the trade will stand for them, or until it is known just what glue is and what it isn't—a time which appears a long way off even today.

Undoubtedly the reader who has been interested in and following the articles on the Properties and Constitution of Glues and Gelatines in the first five issues of the present volume has come to the conclusion that the author has not spent three years of his time in a vain research. Dr. BOGUE has studied the factors influencing viscosity and jell strength, which in turn have long been established as functions of the adhesive properties of glues. He finds that vigorous agitation and prolonged heating tend to break up the physical structure and give a glue of less viscosity and strength. Dehydration if carried far enough produces a reversion of gelatine to an insoluble form called collagen. The effect of electrolytes is largely dielectric. The most probable structure of the colloid glue aggregate is streptococcal. The action of low-grade bone glues in crazing upon drying out thoroughly is due to the non-glue protein content, which does not reduce the vapor pressure of the required water solvent of solid solution to that of the atmosphere.

In commercial interest the outstanding feature is the recommendation that glues be evaluated by a melting-point test. The author demonstrates in the present issue that many errors now prevalent in the viscosity and jell-strength tests can be entirely avoided by a simple melting-point determination. In the final analysis the tensile and shear-strength tests are what the user wants to know, but he cannot take the time such tests require. In a measure, if his product sticks together he can feel assured that the glue he used was at least good enough, but apparently the melting-point test offers considerably more certainty and should therefore be widely adopted.

Readers' Views and Comments

Science the Desecrator

To the Editor of Chemical & Metallurgical Engineering

SIR:—You may have noted that the ubiquitous tinkers have again resurrected the vacuous proposal to mend the Liberty Bell. This time it is aired at length in the *Public Ledger*, and sent broadcast in a pearl of newspaper English by that estimable journal the *Literary Digest*, whose perspicacity in things relating to Science and Invention is attested by its occasional use of my own contributions to your estimable columns.

Passing over an evident play for publicity on the part of some men engaged in welding, the proposal is to mend the crack by arc-welding. In the words of the newspaper:

They would proceed in this fashion: Take first a grain of metal from the crevice of the bell. Have it analyzed by a board of expert metallurgists. Reproduce in the laboratories of the alchemist the identical metal of which the Liberty Bell is composed. When you have the proper alloy you are ready to bring on the electric needle.

Was it Berzelius or was it Stas who was able to obtain the chemical formula for a minute fragment of an unknown mineral? But they are dead. Hence the use of the "board"—ouija board probably is meant. For these expert "metallurgists" would undoubtedly need advice as to how to perform the analysis, being unused to the routine of such work themselves, and unhappily not being able to rely upon Ramsay, that most genial experimenter. But before getting started it would doubtless occur to some of the experts (other than welding experts) who might have sampled a goldmine somewhere that the bell was cast some years before the advent of large melting furnaces, and is the product of at least two dozen crucibles, and each portion had been remelted twice by amateurs, with attendant doctoring! You will agree with me, Mr. Editor, that the alchemist would indeed be needed to reproduce the "identical metal."

Now for the process of welding. Fashion the new metal to be applied into a wire or needle of the welding apparatus. Measure the resistance of the bell and the resistance of the wire after having estimated the amount of steel to fill up the crack. Now to fill in the crack . . . The Liberty Bell is mended just as the surgeon takes a piece of bone from the shin and grafts it on the face to make a new nose—bone for bone and, in this case, metal for metal.

"Steel," did he say? Indeed a strange bell must be this Liberty Bell, well worthy of mending! But he writes prettily, so why be meticulous?

It is asserted by the welders that electricity will also cure the famous bell of its chronic disease. The bell's doctor . . . has held that the bell suffers from a form of distemper. It is to be guarded carefully lest it go all to pieces.

The electrical engineers now prescribe baths for the bell—electrical baths. Heat it electrically and then allow it to cool slowly. This will eliminate the fatigue of the metal. The heat treatment is recommended regardless of the proposed transfusion. The heat, it is reasoned, would preserve the bell by relieving the stress between the metal particles caused by vibration. Constant vibration wears against the relic particularly when it is opened to visitors, as in the recent case when the Spanish novelist, Vicente Blasco Ibañez, clasped and kissed it.

Enough to make even a bell tired!

And so on and so on. Fortunately others than progressive welders are to be consulted before "the invalid bell, with its supposedly fatal wound, shall be summoned into the electric clinic—or left to its fate"! Would not any fate, Mr. Editor, be as good as the electric chair?

I will not impose on your good nature by pointing out in detail what is probably well known to all interested persons except newspaper writers—who evidently do not need to know: that no attempt is made to get an electrode of the same chemical composition as the metal to be welded; that the deposit is changed considerably from its original analysis by the intense temperature; that sound fusion welds cannot be made in bronzes such as bell metal, because the low-melting beta or gamma constituent boils out of the pasty alpha matrix, leaving a veritable honeycomb, and that closed structures of any sort are particularly hard to weld, because upon cooling shrinkage strains are almost sure to reopen the defect.

But for the information of any American who wishes the Old Bell to be preserved against the ravages of time and electrical experimenters it may be confidently stated that the old crack which destroyed the bell's somewhat raucous voice, but thereby canonized it, as well as the new crack discovered about ten years ago, is probably due to the relief of casting or cooling strains, existing in all such pieces, and mitigated ordinarily by careful annealing. Further extension of these defects has been prevented by the late J. Sellers Bancroft, who constructed a concealed spider whose fingers clasp the rim of the bell and are drawn to a central rod by turnbuckles, the whole contrivance being so arranged as to throw compression into that portion of the casting which had split under tensile stresses.

Rest in peace!

MARTIN SEYT.

Cleaning Up Mexico—With Soap

To the Editor of Chemical & Metallurgical Engineering

SIR:—I was much interested in reading your editorial in the issue of June 16 respecting the large importation of soap into Mexico. I have wondered if you thought there might have been ulterior motives in securing such a large quantity of material not usually associated with our ideas of the Mexicans (although I can assure you that there are Mexicans thoroughly familiar with the use of soap and its intended functions).

Only yesterday, however, I was informed by a man recently returned from Mexico that soap was being used for the secret shipment of ammunition in various sections of Mexico; the practice being to slip cartridges into cakes of soap which were then returned to their original boxes and shipped as "soap" to various sections of the country where ammunition was deemed most useful; the boxes with the empty cakes of soap being "returned" to the original point of shipment for fresh loading with cartridges. I cannot vouch for the accuracy of this statement, but it seemed to fit very well with your statement respecting the unusual amount of soap imported by Mexico.

MURRAY C. BÓYER.

Philadelphia, Pa.

British Chemical Industry

(FROM OUR LONDON CORRESPONDENT)

London, July 9, 1920.

SIGNS are not wanting that in common with many other industries in this country, the chemical industry is passing through a transition period in an atmosphere charged with considerable anxiety. Labor unrest is, of course, still with us and is again causing nervousness, but the crucial question of the moment is undoubtedly that of transport. Increases in freight rates and more particularly demurrage charges and inordinate delays and uncertainties in regular deliveries of fuel and raw materials have greatly hampered production and regular output, especially in the case of the larger works. It is hoped that increasing use of road motor transport will ease the situation, and in the meanwhile the proposals of the Transport Ministry for the unification and co-ordination of railway traffic are viewed with scepticism. As regards labor unrest, a typical case is that of Van den Berghs, Ltd., margarine manufacturer, where a strike of the workers for an additional \$4 a week has been firmly refused and the works closed for the time being. The present wages paid are already higher than those at any other factory in the district, while in addition the firm is noted for the excellence of its welfare work. This will perhaps be a test case and there can be little doubt that this example will be followed by many of the large employers of labor. The next few months should show whether the result will be a series of disastrous strikes and lockouts or the alternative—renewed confidence in the future of the country's trade.

COMMERCIAL DEVELOPMENTS

The annual reports of Explosives Trades, Ltd., and Brunner Mond & Co., Ltd., are of great interest, over 60 per cent of the former company's activities being now devoted to interests other than those suggested by its title and including various chemicals, candles, gas mantles, electric lamps, varnishes, metal goods, motor accessories, metal powder, welding and artificial leather. In addition, the company has acquired an interest in General Motors, Ltd., of America, British Dyestuffs Corporation and the British Cellulose Co. and has purchased the British Pluvinsine Co., of Manchester, manufacturing artificial leather. The Chemical & Dyestuffs Traders Association referred to in my last report (see CHEM. & MET. ENG., July 7) has taken offices at 22, Buckingham Gate, London, S. W. 1, and has already taken action with the government authorities in regard to excess profits duty and the status of the association under the Board of Trade. It is interesting to note that its rival, the British Chemical Trade Association, is now furnishing the market reports to the *Chemical Trade Journal*.

The possibilities of oxygen in connection with the carbonization of coal for gas production are attracting considerable attention and it is anticipated that, given a reasonably cheap source of supply as foreshadowed in the report of the Nitrogen Products Committee, considerable saving in fuel is possible together with increased efficiency in the utilization of the available supplies of coal. This problem should be of particular interest in America and other countries possessing adequate water-power resources which are being utilized for the manufacture of nitrogen from the air.

The supply of fertilizers is still inadequate, nearly all countries having recourse to export prohibitions or restrictions. The bearing of the projected developments in the Haber ammonia process has already been discussed, and in the meanwhile the supplies of foreign basic slag are increasing. Much attention is being paid to increased crop production based on scientific methods and the use of mechanical appliances. The electrical treatment of seeds by processes such as the "Wolfryn" process is coming into increasing use and with satisfactory results. The seeds are immersed in a weak solution of salt and a weak electric current is passed for a few hours. After carefully drying the seeds, it is found that on sowing, germination is more rapid and the increase in the crop varies from 20 to 30 per cent, while at the same time the yield of straw and immunity from disease are greatly increased. Arrangements are now being made for the exploitation of the process in all parts of the world and further experiments are to be undertaken in connection with its application to special classes of seeds used in tropical climates.

USES FOR SURPLUS AMMUNITION

In nearly all European countries hundreds of thousands of tons of surplus artillery ammunition are either awaiting disposal or are being broken up into their component parts. In this country the work is proceeding at the national filling factories, hot water being used to wash out the ammonium nitrate and to melt the TNT content in the amatol charge. Many ingenious devices and methods are being applied to the economical recovery of the brass, aluminum and other components. The ammonium nitrate has been largely used as a fertilizer, but so far no use has been made officially of the cordite or other propellant powders and the recovered TNT, these materials being at present merely burned. It is hoped in the near future to find a use for cordite, while it is reported that the TNT can be used as a fertilizer if applied in a sufficiently dilute form. The surplus ammunition in France, amounting to about half a million tons, has been sold to F. N. Pickett & Son, of Wimereux, while the corresponding arrangements in this country with George Cohen & Sons, of London, appear to be hanging fire. The problem of dealing with ammonal charges is probably more difficult than recovery from amatol and attempts are also being made to recover and utilize the saltpeter from the black powder charge of shrapnel shells. The chief problem in these factories is efficient organization and proper handling appliances together with careful physical control of the ammonium nitrate recovery process.

DINNER TO LORD MOULTON

A complimentary dinner is to be given this month to Lord Moulton in appreciation of the valuable services which he has rendered during the war as director general of explosives supplies at the Ministry of Munitions and in other capacities. It is possible that an announcement may be made at this dinner in regard to the scheme of the Federal Council of Learned and Scientific Societies for establishing a chemical headquarters in London and the details should have matured sufficiently by the end of the year to enable the plan to be launched at about the same time as the annual dinner of the Chemical Industry Club in November.

FIG. 1. LOOKING EAST AT DRY-END BUILDINGS

Cyanamide Process Plant at Muscle Shoals

Condensed Sketch of U. S. Nitrate Plant No. 2 Shown by Photographs and Flow Sheets—An Accomplishment Reflecting Credit Upon American Engineers and Builders—Now Stands Idle Awaiting Congressional Action on Government Operation Bill

BY CHESTER H. JONES

LOOKING backward through the facts and fiction about the nitrate situation in general and the cyanamide process as known in the United States through the Muscle Shoals plant in particular, it is noted that the fiction has obscured the truth as presented in the popular press, in the records of the Graham House committee, the report of the proceedings of the Senate Committee on Agriculture and Forestry, the politically colored report No. 998 by Mr. Graham of Illinois, and the subsequent discussions during the second session of the Sixty-sixth Congress. Even a careful perusal of these records by one unfamiliar with the character of the personnel of the conflicting interests would leave him in doubt as to whether the large property in Alabama is valuable or a mere heap of war-time waste. It is not the purpose of this article to enter into the political aspects but

rather to show by the pictured fact that U. S. Nitrate Plant No. 2 is one of the largest chemical plants in the world, that it is for all practical purposes completed and that it is constructed in accordance with the best engineering practice. Laying aside the question of expenditures and motives attributed to its builders it is a marvelous achievement constructed in record time.

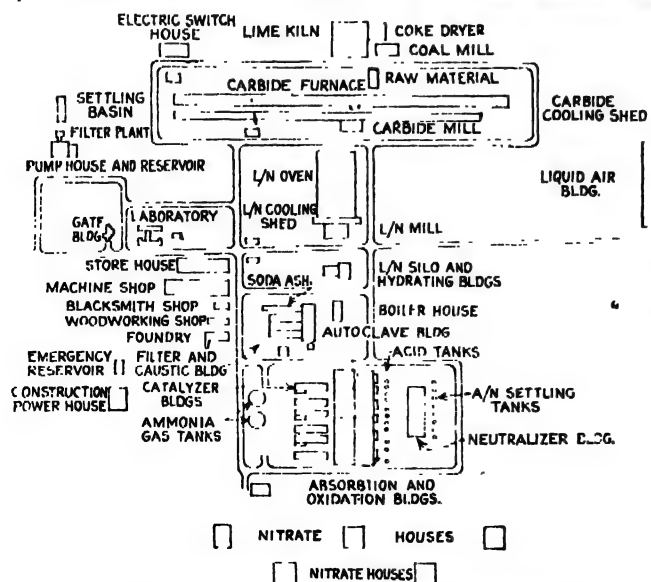

FIG. 2. PLAN OF PROCESS BUILDINGS

FIG. 3. TURBINE ROOM STEAM POWER PLANT

CHEMICAL & METALLURGICAL ENGINEERING, vol. 20, No. 1, dated Jan. 1, 1919, contains a most excellent article by Andrew M. Fairlie on the details of construction and operation written during the construction period, and the actual record of Government operating tests may be found in the July 15, 1919, issue.

Examination of the plan (Fig. 2) gives an idea of the extent of the process buildings, with the exception of the power plant, which lies about three-quarters of

FIG. 1 (CONTINUED). LOOKING EAST AT DRY-END BUILDINGS

a mile to the north of the electric switch house. The section which lies north of the hydrating building is known as the "dry end," while that on the south half is the "wet end" of the process. The flow of material is southward through the plant.

Reading from left to right in Fig. 1, the main power house stacks are visible through the trees. The next low building is the electric switch house, or main substation for the distribution of current to the various process substations. The seven steel stacks locate the limekilns and the twelve steel rectangular stacks are extensions of the hoods over the carbide furnaces. The next long building paralleling the furnaces is the cooling shed. Then comes the carbide mill, the lime nitrogen or cyanamide oven building, attached to the lower of which is seen the cooling shed and lime nitrogen mill. The storage silos and hydrating building are just beyond, but the wet-end buildings are better shown in Fig. 8.

The low buildings in the foreground at the left of this view are the shops, and the building with three monitors to the right is the filter plant. Attached to the rear of this building and directly in front of the brick stack is the autoclave building. These two buildings house the ammonia process machinery. The stack is all that is seen of the process power house which furnishes steam for the autoclaves and the evaporating pans in the ammonium nitrate houses. The long low

building in the background and to the right of this stack is the liquid air building, where nitrogen is made for the lime nitrogen ovens.

In the foreground of the right half of the view are the two ammonia gas holders, and directly behind these the six catalyzer buildings. Beyond these the low shed covering the nitric oxide cooling apparatus is

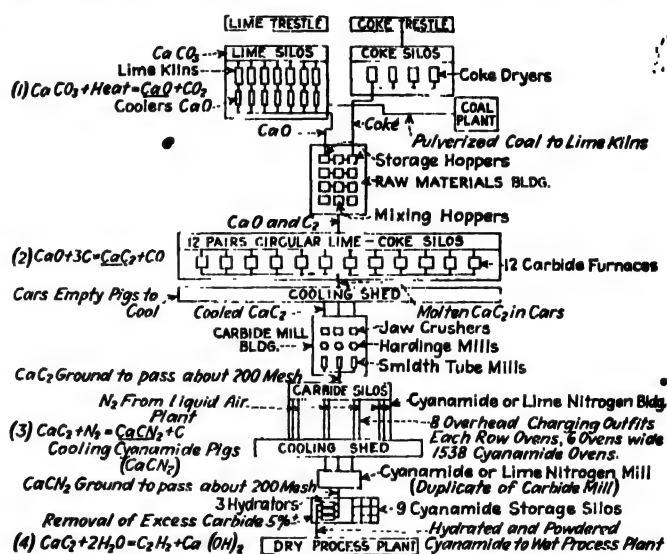

FIG. 5. FLOW SHEET OF DRY PROCESS

FIG. 4. CARBIDE COOLING SHED, LOOKING WEST

scarcely discernible as connecting them with the twelve sets of nitric acid towers standing in the high building beyond. On the extreme right is seen one of the five ammonium nitrate houses with five stacks showing, and a second one in the immediate rear. Three small substations for distributing current to the catalyzers lie between the catalyzer buildings, and the power substation for wet end appears to the right of the autoclave building.

THE PROCESS

Now it must be quite apparent that this mile of houses contains operations of some importance, and it is therefore well worth while to take a look within a few of the more important ones. Let us first take a walk down through the woods to the main power house on the river and see the largest steam turbine in the world, 60,000 kw., made by the Westinghouse Electric Co. It stands in the rear of Fig. 3 with two smaller turbo-excitors in front. If we were to take a walk about the place we could see where the 80-mile trans-

mission line comes in from the Alabama Power Co. and take a look up-river where the new dam is building; examine all the control panels in the switch room and point out the foundation for another turbine, 30,000 kw. As it is we return to the process plant through the bus tunnel, coming outdoors at the electric switchhouse.

Before entering the buildings again, examine the flow sheets (Figs. 5 and 6) and the subsequent views

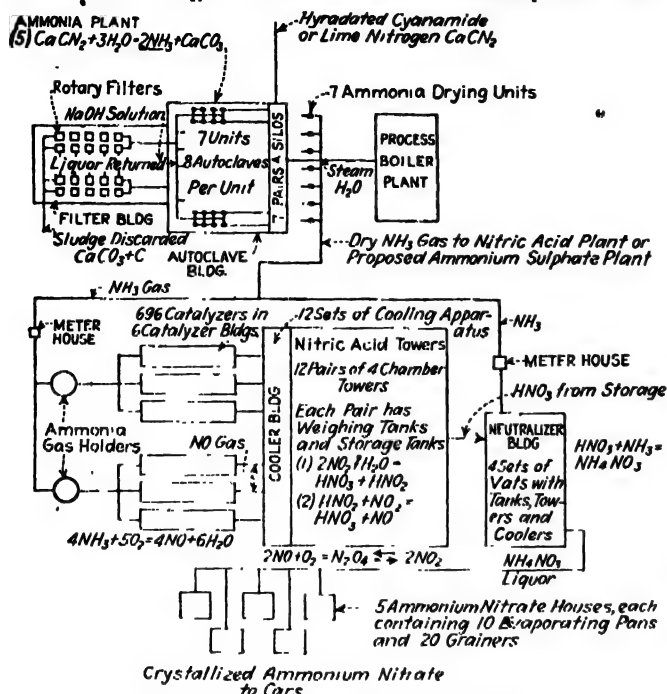

FIG. 6. FLOW SHEET OF WET PROCESS

will be the more easily oriented. Fig. 6 is just a continuation of Fig. 5, and the north to south flow is noted in comparing with the plan in Fig. 2. A sectional flow sheet shown in Fig. 9 gives a more detailed idea of some of the equipment.

Entering the carbide cooling shed (Fig. 4), we see the chill cars in which the molten carbide is taken from the electric furnaces on the right by electric locomotives and the chills subsequently distributed along the floor by the overhead crane seen in the rear. When these have cooled, the crane transports them singly to the concrete tipple pier at the entrance to the mill and shown directly beneath the crane on the left where the contents fall to the jaw crushers within.

Fig. 7 is a view of the mill looking northwest. The

screw conveyor shown at the discharge end of the tube mill conveys the pulverized product to a common system where the output of all three mill units is carried in overhead screws to the lime nitrogen oven room.

Fig. 10 shows only a small portion of the oven room. The rail alongside the ovens carries the charging and discharging machines which straddle each double row. One of these is just visible in the rear of the left-hand row. The ovens are charged at the top by removing the sheet steel covers from the sand-seal on which they rest. The nitrogen is brought over from the liquid air plant in sheet steel conduits.

Fig. 11 is an interior view of the liquid air building, showing the largest installation of high-pressure air compressors in one plant. There are twenty-three in all, Sullivans, Norwalks and Ingersoll-Rands, of which five furnish service air for the shops and the acid lifts in the wet end, and eighteen operate on the liquid air production. The air columns are seen on the right and with a closer view in Fig. 12. There are thirty-six of

FIG. 7. CARBIDE MILL.

these operating independently but with each compressor serving two units. The higher tanks shown at the end of the row are caustic towers employed for washing the air before it enters the compressors. Service cranes operate in both bays of this building.

FIG. 8. LOOKING EAST AT WET-END BUILDINGS

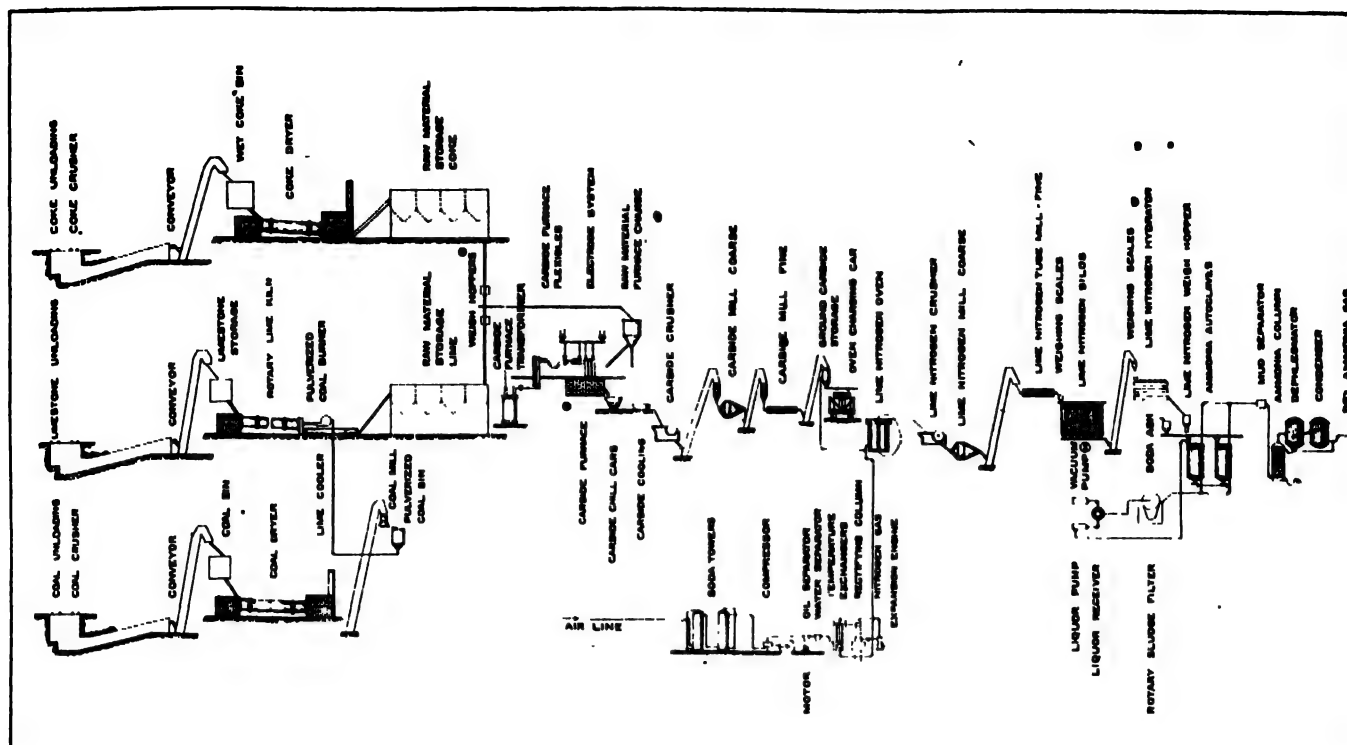

FIG. 9. SECTIONAL FLOW SHEET OF PLANT

Passing over the ammonia process, which is one of the secret operations, we come to the ammonia oxidation plant and see in Fig. 13 the interior of one of the six catalyzer buildings. The ammonia enters at the top of the aluminum boxes and passes downward into the brick flue as nitric oxide gas, when it is carried to the cooling, oxidation and absorption systems to produce nitric acid.

Fig. 14 is interior of one of the five ammonium nitrate houses. There are five rectangular evaporating pans on each side bay whence the concentrated liquor is drawn to the twenty grainers for crystallation. When the sirupy liquid is changed to sugar-size granules in these grainers the handwheel gates are opened, permitting the charge to flow onto the floor down the center, whence it is shoveled through the grizzly openings to a belt conveyor which carries it to storage or into the cars.

Rated capacities of apparatus in the plant are:

Coke Driers. There are four coke driers, three for operation, one for spare; capacity, 111 tons each for 16 hr.

Coal Driers. There are two coal driers, one for operation, one spare; capacity, 170 tons each for 16 hr., or at rate of about 10 tons per hr. per drier.

Coal Mills. There are four coal mills, three for operation, one spare; 3½ tons each per hr. for 16 hr.

Limekilns. There are seven limekilns, five for operation, two spare; 100 tons per day each.

Furnaces. There are twelve furnaces, ten for operation, two spare, producing 48 tons of 80 per cent carbides each in 24 hr. There is 50 lb. of electrode consumed per ton of carbide. There is 12 lb. of CaC_2 produced per horsepower-day; 124 kilowatt-days required per ton of 80 per cent CaC_2 , or 29.76 kilowatt-hours operating at an 84 to 87 per cent power factor.

Mill Units. There are three mill units, two per actual operation; 16 hr. per day; 240 tons each per day or 15 tons per hr. per unit.

Lime Nitrogen Ovens. There are 1,538 lime nitrogen ovens, 1,500 for actual operation and 38 spares. Each oven takes a charge of 1,600 lb. of carbide (1,570 actual) through a 60-hr. cycle or 1,200 tons of CaC_2 in

FIG. 8 (CONTINUED). LOOKING EAST AT WET-END BUILDINGS

Catalyser building, interior. Bottom left, Fig. 14. Ammonium nitrate house. Bottom right, Fig. 15. Section of construction camp.

60 hr., or 1,500 ovens every 2½ days, equals 510 ovens per day. This produces 600 tons of lime nitrogen daily.

Lime Nitrogen Mill. There are three mill units, two for operation, one spare; 16 hr. operation, 300 tons each.

Hydrating Building. There are three hydrators, two for operation, one spare; rated capacity 30 tons per hr. each.

Autoclave Building. There are seven autoclave units, six for operation, one spare; rated 100 tons per unit per day.

Filter Building. There are twenty filter wheels, fifteen for operation, five spare; rated capacity, 15 tons of sludge per filter in 24 hr. Total estimated tons of sludge, 720.

Nitric Acid Group. There are 696 catalyzers, one catalyzer producing 900 lb. 100 per cent HNO_3 for 24 hr.

FIG. 16. STREET IN PERMANENT VILLAGE

One nitric acid unit produces 22.5 tons of 100 per cent HNO_3 with 100 catalyzers in operation per 24 hr.

Neutralizer. There are four neutralizer units, each producing 100 tons of 100 per cent NH_4NO_3 , three for operation, one spare.

Ammonium Nitrate Houses. Three hundred tons of ammonium nitrate total grained. Each house rates 60 tons per day. Each evaporating pan produces 8 tons per day. Forty pans for operation, ten spares. There are 100 grainers, eighty for operation, twenty spares. Each grainer handles four tons per day.

CONCLUSION

Neither space nor readers' patience will permit the penning of a eulogy on this work of our own engineers and craftsmen. It was made in the United States; the machinery, instruments and apparatus were turned out in our own factories; the special tile and chemical fittings testify to the achievements of our clay-working industries; the raw materials, the electrical equipment—but why continue, the story tells itself in pictures. Noble minds of many men have fabricated their souls' spirit into a being of metals and silicates which now lies sleeping in the Alabama sunshine while Government executives fiddle and politicians whittle. May the day soon come when it will be awakened to again sing a part in tune with the nation's industry and bring thereby all honor to these American engineers and workmen.

Prices Fixed on Sicilian Sulphur

By a decree of the Italian Ministry of Industry, Commerce and Labor, maximum selling prices on different grades of crude and refined Sicilian sulphur are established, to take effect retroactively from May 1. The decree is dated May 24 and appeared in the *Gazzetta Ufficiale* of May 29. The prices fixed by the decree for sulphur, refined or worked, apply to certain ports in Sicily which are taken as basing points. For instance, Catania, Licata, Porto Empedocle and Termini Imerese are named as the four Sicilian seaports for which the following base prices are given as the maximum per 100 kilos:

	Lira per 100 kilos.
Sulphur, advanced beyond crude state:	
Refined, in cakes.....	84.26
Refined, in rolls.....	87.26
Pure sublimed.....	108.62
Crude ground.....	77.46
Refined and ground:	
Content—	
From 60 to 65 per cent.....	96.90
From 65 to 70 per cent.....	98.35
From 70 to 75 per cent.....	99.98
Refined and fanned:	
Content—	
From 75 to 80 per cent.....	101.35
From 80 to 85 per cent.....	103.67
From 85 to 90 per cent.....	106.66

To each of these prices as tabulated is to be added the charge of 5 centimes per 100 kilos, or 0.5 lira per metric ton, as a contribution toward the support of the Sicilian Sulphur Consortium, of which all producers are obliged to be members. The given prices are f.o.b. vessels or loaded in cars at the station of any one of the four ports selected as basing points. To determine the maximum allowable prices for other points in Sicily, actual transportation charges from one of the basing points to the destinations in question may be added. Furthermore, in the case of refined sulphur in cakes, allowance may be made for loss in transit not exceeding 1 per cent.

The prices of crude grades of sulphur shipped to Italian destinations outside Sicily are to have added to them 120 per cent of transportation costs, the extra 20 per cent to cover cost of handling, with a permitted allowance for loss of weight in transit not to exceed 2 per cent. The prices of worked sulphur at points outside Sicily are to be calculated in the same way, that is, by adding 120 per cent of the freight charges to the base prices, but the maximum allowance for loss of weight in transit cannot be greater than 1 per cent.

On crushed sulphur ore the maximum prices per 100 kilos, f.o.b. cars at shipping point and exclusive of cost of bags, have been set by the same decree as follows:

	Lira per 100 Kilos
Sulphur content of ore:	
From 25 to 30 per cent.....	21.85
From 30 to 35 per cent.....	25.15
From 35 to 40 per cent.....	28.45
From 40 to 45 per cent.....	31.75
From 45 to 50 per cent.....	35.05

For the resale of worked sulphur and crushed ore an addition of 2 per cent is allowed on the fixed purchase price as it is prescribed by the decree or calculated on the basis of transportation charges in lots of 1 metric ton or more. On the resale of lots amounting to less than 1 metric ton an addition of 4 per cent is permitted in order to yield the dealer's profit.

The ministerial decree which establishes the prices set forth above does not set them for sulphur of fineness exceeding 90 per cent, washed sulphur for medicinal purposes, and flowers of sulphur, all of which are specifically exempted from the purview of this particular price-fixing measure.

Small-Scale Manufacture of Barium Chlorate

BY TREADWAY B. MUNROE

THERE has recently been published by the Ordnance Department, U.S.A., in three volumes, an excellent work entitled "Military Pyrotechnics," by Henry B. Faber, dean of the Pyrotechnic Schools of the Department, the third volume of which is devoted to "A study of the chemicals used in the manufacture of military pyrotechnics." In this volume there is given for each substance its history, occurrence in nature, method of manufacture, availability of supply, uses other than in pyrotechnics, physical properties, chemical properties, function in pyrotechnic pieces, qualitative analysis, quantitative analysis, specifications and discussion of specifications. Among these chemicals barium chlorate occupies an important place, and since examination shows that the only methods given in this treatise for the preparation of barium chlorate are through (1) the metathesis of barium chlorate with sodium chlorate, (2) the chlorination of barium carbonate, and, especially (3) "the electrolysis of barium chloride," which is said to be the method by which "the barium chlorate of commerce is invariably prepared," it seems proper to place on record an account of a recent emergency use of Wheeler's method¹ in the preparation of this substance.

During the early summer of 1917 the Navy Department laboratory at Indian Head, Md., was unable to obtain any bids for supplying barium chlorate for use in its green signal rockets and flares. Up to this time this material had been imported from Germany at a very reasonable price. Attempts were made to substitute compositions made from various copper salts and potassium chlorate, with sugar, flour and other combustible substances, but the brilliancy of the green light obtained with barium chlorate mixtures apparently could not be duplicated.

AID TO NAVY DEPARTMENT

This condition was brought to our attention by the Government contractor who ordinarily supplied the requirements, with the statement that the shortage was acute, that he had been unable to obtain this material or enlist the interest of others in its manufacture, and that if we could arrange to make up to 500 lb. in the laboratory it would allow the department time to arrange for the development of a permanent source of supply. Under these conditions we promised to make it.

A survey of the materials immediately available having shown a sufficient supply of sodium chlorate, hydrofluosilicic acid and barium carbonate at hand, it was determined to proceed by Wheeler's method as shown in the following expressions:

All the substances employed were commercial. The determined amount of sodium chlorate was dissolved in the least quantity of hot water possible, this was then added to a known quantity of the hydrofluosilicic acid in a stoneware jar and allowed to stand until the sodium

fluosilicate formed had settled; the chloric acid was then decanted to another stoneware jar, the sodium fluosilicate stirred up with hot water, allowed to settle and the weak acid decanted and added to that in the other jar. The chloric acid was then neutralized with barium carbonate, concentrated in galvanized washtubs and allowed to crystallize; the mother liquid was saved and then several portions batched together would be evaporated to dryness and this impure chlorate used in place of part of the sodium chlorate to prepare the chloric acid. The barium chlorate was crystallized a second time, dried on a fruit evaporator, ground to better than 80 mesh in a coffee burr mill and sacked. Something over 400 lb. was made and proved to be satisfactory. The work was discontinued when the Navy Department was able to interest other parties in manufacturing this material electrolytically.

Theoretically 1 part of sodium chlorate yields about 1½ parts of barium chlorate; by this method we obtained a yield of but 1 to 1, the chief loss being due to the difficulty in separating the chloric acid from the sodium fluosilicate.

DIFFICULTIES ENCOUNTERED—INTERESTING SIDELIGHTS

Attempts were made to use various stone and artificial filtering mediums with suction, but owing to the slimy character of the precipitate they invariably clogged. A centrifuge would probably have solved this difficulty, but time would not permit us to secure one. Another difficulty was that the chloric acid fumes given off from the hot solution killed the trees and other vegetation adjacent to the laboratory and attacked the eyes, throat and nose of the operator to such an extent that he was finally compelled to wear a British army gas mask nearly continuously during his work.

It is of interest to note that when this material was crystallizing from solution if the crystal formation was disturbed then both sound and green flashes of light were observed. This occurred in glass, galvanized iron and wooden containers. Reference was found in the literature to the fact that sound is given off through agitation of the crystals, but we have at no place noted it recorded that light is given off also.

It is also of interest that the production of barium salts in this country, other than the natural barium compounds, was so new at that time that this small production was taken into account by the Geological Survey in its 1917 report.

Some of the crystal groups obtained in the course of this work were quite attractive. One of them, in fact, was presented to the National Museum and deemed by its curator worthy of a place in its exhibits.

Proposed Law to Permit Exportation of Pulpwood From Burned-Over Lands in Canada

A bill was introduced in the Provincial Legislature of Ontario on May 20, 1920, by the Minister of Lands and Forests, in which authority is provided for the exportation of pulpwood from areas which have been burned over by forest fires.

The object of the bill, as explained by the Minister, is to get the pulpwood cleaned off in these districts quickly in order to prevent a recurrence of forest fires. The districts to be cleaned up in this manner are not large, though the bill provides that the government shall decide what areas are included in the measure.

Early Commercial Electrolytic Cells*

Reminiscences of the Pioneer Chlorine Cell Work Done at Rumford Falls, Maine, and Berlin, New Hampshire—Graphite Electrodes Introduced—Porous Diaphragm Cell Developed

By CHARLES B. BARTON

THE paths of the early workers on electrolytic cells were not strewn with roses. They were very rocky. I speak from experience, for I think I have been continuously in the business longer than any other man in this country. In September, 1894, I went to work for the old Electro-Chemical Co. of Rumford Falls, Me., as a laborer; twenty months later I was made superintendent of the plant, and have held that position there, and subsequently in Berlin for the Brown Co. This makes twenty-six years of experience.

The original cells in Rumford Falls were the old bell-jars, with an asbestos diaphragm, approximately horizontal. The anodes were of retort carbon and were cast in lead, a projecting portion coming through the top of the belljar, to which was connected the positive wire. The cells were supposed to take about 100 amp. each and were run in parallel in the iron cathode tanks, the tanks being connected in series. The diaphragms of these cells had to be changed very often, the units were too small, and when I entered the employ of the company in 1894 it had discarded this type and was changing the type of cell.

These second cells were square boxes about 24 x 24 x 24 in., the top and upper third of the outside being made of slate with a slate cover, a wooden leg on each corner and a wooden bottom. Around the open part asbestos paper was wound for a diaphragm and outside of this wire netting, the netting being turned on the bottom of the cell so as to give electrical contact with the bottom of the iron tank, which held the cathode bath. The anodes were of gas carbon, with the ends cast in lead and space between the central anode proper, and the asbestos diaphragm was filled with lumps of broken retort carbon, the object being two-fold: To hold the diaphragm against the cathode and to bring the active anode surface closer to the cathode surface. About 500 of this type cells were discarded and another type later installed.

The third type of cell was a slate box with gas retort carbon anodes and no packing between the anode and the diaphragms. They were of various sizes, a large number about 36 in. in length x 6 in. wide and about 18 in. deep. These cells are very similar in construction to cells in commercial operation today. They were, however, soon discarded in favor of another type installed.

The fourth type was a distinct departure from the previous types. It was a large unit and was contained in a cathode tank, 9 ft. long, 5 ft. wide and 18 in. deep. A wooden frame of 4 x 6 in. lumber was laid in the bottom of the tank, on this frame a grid of iron made of 3 x 1½ in. iron stock was laid and part of the irons were extended and bolted to the tank to make contact with it.

These irons were inclined to the horizontal so there was a pitch of 2 in. to the foot. On top of these irons a wire netting was placed to act as the cathode proper, and on top of this cathode a diaphragm of asbestos paper was laid. The side walls of the cells were made of red brick and the diaphragm was cemented in with quick-hardening cement. The covers were slate and the anodes were platinum wire. About fifty of these were operated during the spring and summer of 1898. The design was good and with the substitution of perforated metal plate for the iron grid and concrete side walls for the brick and wood the same cells are running today and are running efficiently.

TRANSFER OF THE ELECTRO-CHEMICAL CO.

The plant of the Electro-Chemical Co. of Rumford Falls closed in the fall of 1898 and part of the plant and operating personnel were transferred to Berlin, N. H., to make chlorine for bleaching the pulp of the Burgess Sulphite Fibre Co. T. P. Burgess, the manager of this plant, believed in the future of electrolytic chlorine and he believed that experience was the most valuable asset he could buy. He bought the experience of the Rumford Falls plant and he paid a very low price for it. The stockholders of the Electro-Chemical Co. shouldered their loss. The stockholders of American electrolytic chlorine and caustic soda corporations owe to stockholders of the old Electro-Chemical Co. at least a debt of gratitude. Let us analyze the reasons why the different cells developed at the Rumford Falls plant were not a success commercially. The first cells of the old belljar type failed because they were too small a unit, the diaphragm broke too often, and they were connected in parallel in the cathode tanks. The second cells failed because of the wooden construction of the body, the fact that the anode compartment was filled with broken pieces of carbon so as to give very poor circulation, and because of the method of making electrical contact to the anodes, which, you will recall, was by casting the upper ends in lead. The lead soon became oxidized at the points of contact, and this caused a rising voltage and uneven distribution of current in the tanks, for these cells had the fault of the previous ones, that they were connected in parallel.

The third type of cells failed because the same method of making electrical contact with the anode, casting in lead, was used, because the cells were connected in parallel, because too small a chlorine chamber was left in the cell and because the material of which they were composed, slate, was not the proper material of which to make cell bodies.

The final type of cell developed at Rumford Falls was a commercial failure there because the stockholders did not care to sink any more money in the plant. It was a success in Berlin.

*Read before the American Institute of Chemical Engineers, Montreal, June 28, 1920

I think it is proper at this time to state that E. A. LeSueur had no active part in the management of the Rumford Falls Electro-Chemical Co. until the original development funds were about all spent. After the original management had demonstrated it could not run the plant at a profit he was made manager, but there was so little money available for experiments and development that the plant could not be developed to a commercial success. The offer from the Burgess Sulphite Fibre Co. to take over the plant came while the plant in Rumford was still in operation and was accepted as an easy way out of an exceedingly uncomfortable financial condition.

TRouble WITH CARBON DIOXIDE

It is now time to mention a few of the difficulties of operation encountered in the infant industry. The draft for moving the chlorine was originally obtained by introducing a pipe into the draft tube of the water wheels. It was later produced by steam siphon. The gas pipes to all the first cells were of lead and of small diameter, so that they were always clogging up. The brine was fed to the cells by means of a dipper and a funnel through a hole in the top of the cells, and when acidulated brine was introduced to a cell whose anode compartment was full of sodium hypochlorite the foam immediately clogged the gas pipes and imparted a green tint to the atmosphere. In fact, the atmosphere of the cell houses was usually slightly green and all men who entered the cell houses wore muzzles. A cell whose anode compartment is contaminated with alkali always runs at a low current efficiency. The oxygen liberated at the anode immediately attacked the amorphous carbon and formed CO, with which the chlorine was contaminated. The lime spread in the bleach chambers absorbed the CO, and this lowered the test of the bleach so that it was not always salable, in competition with English bleach. It was observed, however, that the CO, always combined with the top lime and formed a hard crust. It was necessary to skim off this top crust in order to produce merchantable bleach.

This difficulty finally led to experiments with platinum anodes, which seemed to promise elimination of our troubles. It was necessary because of financial reasons to use the smallest amount of platinum possible. Mr. LeSueur produced a platinum anode which was based on the idea of the electric light bulb. Sixteen pieces of platinum wire about 4 in. long were sealed in a glass tube in the same manner as was formerly usual in making light bulbs. About 1 in. of wire was left inside the tubes, and the outside wires, which were flattened, were spread like the spokes of a wheel at right angles to the tube. Electrical contact to the inside wires was made by a drop of mercury. It was necessary to have a horizontal diaphragm to use this anode, and they were used in the last type of cell installed in Rumford Falls.

The money for this last installation was very meager. The directors wanted a profit or they wanted to close down the plant, and not enough platinum anodes were allotted to each cell to carry the load. The result was that many of them cracked. This threw the load on the remainder, with the result that the cells ran at very high voltages, from 5.5 to 7.5 or 8 per cell, at 1,200 amp., with about 30 sq.ft. of diaphragm per cell. This produced a very peculiar and puzzling result. The temperature rise was so great that sodium chlorate was formed in large amounts; the caustic liquor going

to the kettles contained only about 2 per cent NaCl, but the finished product would contain about 10 per cent. When the reason was discovered all caustic liquor was treated with potassium chloride, and we were obliged to go into the manufacture of chlorate of potash. It was at the time of the Spanish-American war and chlorate of potash, being contraband, shot up in price, so that it really was a blessing in disguise, and allowed us to weather the gale for a little longer. However, after the offer from the Burgess Sulphite Fibre Co., we soon shut down and thus closed the first commercial American plant of porous diaphragm cells for the production of chlorine and caustic soda.

McDonald and Mercer were foremen of the cell houses in Rumford Falls. H. K. Moore had his first experience with cells in the employ of the Rumford Falls plant. The Nelson cell was born of experience with the McDonald cell, which was a copy of the third type of LeSueur cell. I should like to read some claims of the LeSueur cell patents granted in 1891, now lapsed.

2. An electrolytic cell comprising a bell of earthenware, a positive electrode therein, a diaphragm covering the mouth of said bell, a negative electrode, and a tank in which said bell is placed, the level of the liquid within the bell being higher than that of the liquid outside the bell, whereby the diaphragm is prevented from bulging, substantially as set forth.

3. An electrolytic cell comprising a combination, with a tank to contain liquid, of a bell in said tank, positive and negative electrode, and a flexible diaphragm between said electrodes and covering the bottom of said bell, said diaphragm being adapted to maintain the liquid of the positive electrode side of the said diaphragm on a higher level than that of the liquid of the negative side of the diaphragm, whereby the diaphragm is kept from approaching the positive electrode, substantially as set forth.

In the LeSueur electrolytic patents the principle of having on the anode side of the diaphragm a greater hydrostatic head than is carried on the cathode side is first mentioned. Unless I am greatly mistaken, these patents were the foundation of all electrolytic porous diaphragm cells, and credit should be given E. A. LeSueur as being the real founder of the industry.

EARLY WORK AT BERLIN

When we moved to Berlin, N. H., in October, 1898, it was with the purpose of making bleach liquor for bleaching the pulp, and letting the caustic run to waste. The plant was a success from the start, though handicapped in various ways. Seventy-two cells were installed to run at about 1,000 amp. The writer should have known better from past experience, for he made a mistake in starting the original plant in using the exhaust steam from the engine that furnished the auxiliary power to heat the water that was run in the cathode compartment to flush out the cathode liquor. This made the cathode liquor so active that it diffused into the anode compartment to such an extent that it seriously affected the efficiency of the plant. This mistake, was, however, soon rectified.

The power for the operation of the cells in Berlin was bought under a peculiar arrangement. The power from four water wheels, a maximum of about 1,000 hp., was contracted for at a low figure, when there was water enough in the river to run these wheels, the six other wheels in the same power house having prior right to the water and running the sawmill. The result was that the power was very uneven and in the winter of 1899-1900 it was necessary to shut down.

The writer moved to the sulphite mill and set up some

experimental cells in the digester building. There we ran experiments for several months, mostly on cells of the Moore type, and with the new Acheson graphite, which had just then come on the market. In plotting the variables, and trying to find why some cells ran better than others, I found that by manipulating the flow through the diaphragm in proportion to the amperes going through the cells, using saturated brine, I could get any results I desired within certain limits. If we wanted to get 97 or 98 per cent current efficiency we simply increased the flow to the point necessary. This would decompose about 50 per cent of the salt in the brine fed to the cell. If we wanted to decompose about 60 per cent of the salt we reduced the flow to the point on the curves that would give this figure, and would get about 90-91 per cent current efficiency.

ACHESON GRAPHITE ELECTRODES

We immediately designed a cell and installed 160 of them, the original Moore cells, the first cells run commercially with unsubmerged cathodes. There were mistakes made in the construction. The frames were made of slate put together with wood screws. They were installed in a single row, on about 8 in. centers. The graphite was not impregnated, the brine was not purified. The gas outlets were 1 in. glass tubes. The gas space in the cells was too small and they vomited chlorine continuously. We lived, I don't know how, with them nine months, and then threw them all out the back windows, and called it good riddance. The principle was all right, but we did not work it out to its logical conclusion. I had been steeped in chlorine for nine months and cared nothing about principles or conclusions. Now, however, we had Acheson graphite. The graphite from the Moore cells was used in the LeSueur cells and we soon began to get wonderful results for that time. The voltage drop on individual cells was 4 to 5 volts, instead of 5.5 to 6.5 with a platinum anode. The production jumped, while the power required per ton of bleach was lowered from 100-125 hp. to 80-90 and, of course, in later years to 60-70. The real feature of the electrolytic cell dawned with Acheson graphite anodes. The original plant in Berlin had grown from seventy-two cells, with a production of 3 to 6 tons of bleach per day, to a plant with about 800 cells and a maximum production of 80 to 90 tons 35 per cent bleach. The water wheels that formerly furnished power for the sawmill and caused the shutting down of the bleach plant wheels are now furnishing power for the cells as well as all the other wheels in the next lower power house, and half the wheels on the one below that. We have installed 160 of the latest type of Allen-Moore cells, which resemble the original ones only in principle. H. I. Allen, with H. K. Moore, developed the cell from the point where we left it.

About the same time that the LeSueur cells were started in Berlin, N. H., in 1898, an installation of Carmichael cells was started at the Westbrook, Me., plant of the S. D. Warren Paper Co. These cells used platinum wire anodes and the gravity principle of separation. They were not a commercial success.

The history of the development of the diaphragm electrolytic cell emphasizes the well-known point that new processes are best developed by a well-organized corporation, engaged primarily in some other business that can bear the financial burden of experimental failures and keep on until success crowns its efforts.

What Constitutes Unfair Trade Practice?

THE recent citation by the Federal Trade Commission of firms operating in restraint of trade may have caused the question to arise in the mind of the reader as to just what constitutes unfair trade practice. As a matter of general information the following list of unfair methods, taken from a recent address of a member of the Federal Trade Commission, William B. Colver, is given:

Misbranding of articles as regards the materials or ingredients of which they are composed, their quality or their origin or source.

Adulteration of various products, misrepresenting them as pure or selling them under such names and circumstances that the purchaser would be misled into believing them to be pure.

Bribery of buyers or other employees of customers with money, valuable presents, etc., to secure new customers or induce continuation of patronage. The payment of specified percentages of the purchase price of commodities to employees of customers who practically control the purchases through their recommendations has been and still is deplorably prevalent in some industries. The total amount of these commissions runs into enormous sums. If the practice can be prevented it will save much money to the sellers of the goods, making price reductions possible or rendering further increases in prices unnecessary, and tend to better business morals. A variation of this practice is found in bribing an employee of a customer to introduce foreign substances into the product of a competitor, spoiling its usefulness and thus procuring the business of the concern. The commission has suggested to Congress that a Federal criminal law against commercial bribery should be passed, and this suggestion has been vigorously approved by many great associations of business men.

UNFAIR METHODS AGAINST COMPETITORS

The payment of bonuses by manufacturers to the salesmen of jobbers and retailers, with or without the knowledge of their employers, to procure their special services to push the goods of the manufacturer has likewise been condemned.

Procuring the business or trade secrets of competitors by espionage on their plants, by bribing their employees or by similar means.

Procuring breach of competitors' contracts for the sale of commodities by misrepresentation or by other means.

Enticing away of valuable employees of competitors in such numbers as to disorganize, hamper or embarrass them in business.

Making of false or disparaging statements respecting competitor's products, his business, financial credit, etc.

False or misleading advertising. There are obviously many varieties of this practice. A few of the statements condemned have been those respecting prices at which goods are sold, methods employed in the advertiser's business which if true would give it advantages over competitors in the matter of prices; misrepresentation that goods are sold at cost; false claims to Government indorsements of products, and advertising special cut-price sales at which goods are sold at the usual or ordinary prices.

Widespread threats to the trade of suits of patent

infringement for selling or using alleged infringing products of competitors, such threats not being made in good faith but for the purpose of intimidating the trade. False claims to patents or misrepresenting the scope of patents. Statements of this character have been at times sufficiently broad to give claimants a monopoly of an industry. In one instance a manufacturer procured a patent on a variation of a well-known and long used process of manufacturing a product and thereafter claimed to have a monopoly of the product, threatening all competing manufacturers and the trade with suits for infringement.

Tampering with and misadjusting the machines sold by competitors for the purpose of discrediting them with purchasers.

Trade boycotts or combinations of traders to prevent certain wholesale or retail dealers or certain classes of such dealers from procuring goods through the usual channels.

Passing off of the products of one manufacturer for those of another by imitation of product, dress of goods, or by simulation of advertising, or of corporate or trade names.

Misrepresenting the materials of which competitors' products are composed, and the financial standing of competitors, preventing competitors from procuring advertising space in newspapers or periodicals by misrepresentation respecting their financial standing or other misrepresentation calculated to prejudice the advertising medium against them.

Misrepresentation in the sale of the stock of corporations.

Sale of rebuilt articles of various descriptions—for example, rebuilt automobile tires and of old motion picture films slightly changed and renamed—as and for new products.

Harassing competitors by fake requests for estimates on bills of goods, for catalogs, etc.

Giving away of goods in large quantities to hamper and embarrass small competitors.

Sales of goods at or below cost to accomplish the same result.

Sales of goods at or below cost as "leaders," coupled with statements misleading the public into the belief that they were sold at a profit by reason of the sellers' superior facilities for manufacturing, purchasing, etc.

Bidding up the prices of raw materials to a point where the business is unprofitable for the purpose of driving out financially weaker competitors.

UNFAIR METHODS IN DEALING WITH CUSTOMERS

Loaning, selling at cost, or leasing to dealers at nominal considerations, storage and merchandising outfits such as pumps and tanks for gasoline and coffee urns for coffee, on the condition that they be used only in the distribution of the products of the manufacturer. The effect of the widespread use of this method, is to render it very difficult, if not impossible, for competitors coming into a field to find purchasers among the trade, since the equipment of dealers must be used only in the distribution of products of particular manufacturers. To illustrate the consequences of the practice, in one instance a very large corporation which had been engaged in foreign trade sought, after the opening of the war, to go into domestic business, and found itself practically unable to sell because of outstanding equipment contracts. The expenditure of hundreds of thou-

sands of dollars was required in purchasing the business of concerns with outstanding leases or contracts for the use of equipment before any substantial business could be done. Only the great financial strength of the corporation enabled it to enter the business at all. Of course, in the end the public paid the bill. Such loans or leases of equipment have been prohibited in several industries.

There is the use by monopolistic concerns of concealed subsidiaries for the carrying on of their business, such concerns being held out as not connected with the controlling company.

Intentional appropriation or converting to one's own use of raw materials of competitors by diverting shipments, etc.

Giving and offering to give premiums of unequal value, the particular premium received to be determined by lot or chance, thus in effect setting up a lottery.

Any and all schemes for compelling wholesalers and retailers to maintain resale prices on products fixed by the manufacturers. The commission is seeking with the sportsmanlike aid of the Beech-Nut people, to have this question settled by the United States Supreme Court in a test case. Meanwhile the commission has urged upon Congress a law that will recognize and protect with proper safeguards the good-will property right which a maker of identified goods may have after he has parted title to the goods themselves.

Combinations of competitors to enhance prices, maintain prices, bring about substantial uniformity in prices, or to divide territory or allot customers.

In addition to the practices already enumerated there have been cases where a number of practices associated together were condemned because of their combined effect unduly to restrict competitive opportunity and where it could not be said probably that any single practice standing alone would have been condemned. A clear idea of these can probably only be had by reading the findings and orders of the commission in the particular cases.

ATTITUDE OF THE SUPREME COURT

Though the commission was organized in the spring of 1915, only one decision of the Supreme Court of the United States has thus far been had interpreting the provisions of Section 5 of the commission's organic act. This decision actually determined only a point the commission had not pleaded that the particular practice had a dangerous tendency actually to restrict competition. It appears from the opinion, however, that the court is inclined to establish two classes of practices as being in violation of the act: First, those practices which have heretofore been regarded as opposed to good morals because characterized by deception, bad faith, fraud or oppression, and second, practices regarded as against public policy because of their dangerous tendency unduly to hinder competition or create monopoly. Apparently, if a practice have this dangerous tendency it will be regarded by the court as in violation of the act, even though not heretofore declared to be an unfair method of competition.

By far the greater part of the practices thus far condemned by the commission fall within the first class described by the court. Some of them depend for their unfairness, however, on their tendency unduly to hinder competition. Whether such a practice has this tendency depends on the proof in the particular case.

Elements of Design of a Copper Refinery

Certain Features of a Refinery Must Be Settled First, Such as Location, Capacity, Current Density, Tank Dimensions, General Wiring and Switchboard Diagrams, Size of Anode and Cathode Furnaces, Purification System and Type of Silver Refinery

BY LAWRENCE ADDICKS

UP TO the present time electrolytic refining has been conducted almost exclusively in the United States, about 80 per cent of the world's production being treated here. This has been due to several factors. The North American continent has produced the great bulk of the world's output of copper, metallurgical operations have been developed on a larger scale in America than elsewhere and the local copper production has been largely consolidated into a few large groups each capable of supporting one or more large refineries.

LOCATION

Since the war the nations of Europe have developed a new desire to control key industries complete within their own borders, home or colonial, and new tariffs, trade routes, etc., are likely to cause the building of various new refineries. In general the factors associated with the movement of copper from mine to market, rather than those directly connected with refining, such as cost of power, are likely to control the location of a plant. Unless a plant is built to refine a large tonnage from a single group of mines, care must be taken when determining upon its location to consider breadth of both copper supply and market. The result has been to group a number of the American refineries around the port of New York because at that point rail shipments from Western smelters and ocean arrivals from South America conveniently join steamship deliveries to Europe and railroads to New England mills.

One of the advantages of having a refinery close to an Atlantic port is that orders can be filled promptly in the particular shape specified, enabling the European customer to play close to a fluctuating market, which at times would result in a preferential sale. Another objection to locating a refinery at a far distant mine is that a long time elapses between the production of a wirebar and its actual rolling, so that there is no prompt independent check upon the quality of product the plant is turning out. Aside from these considerations, the availability of a suitable coal for furnace work and the existence of a good boiler water together with ample water for condensing must be looked into.

CAPACITY

In the same way external considerations may justify the operation of a plant of a capacity far below the economic size, but the latter is a point of universal interest. In these days of economic disturbances it is very hard to state anything in terms of absolute cost, but a relative diagram may be made, showing with reasonable reliability the relation between plant capacity and operating cost. This has been attempted on a percentage basis in Fig. 1, where it is shown that not much is to be gained, in so far as cost is concerned, by making a plant of larger capacity than 200,000,000 lb. of copper per

year. Even this figure, however, is beyond the reach of any but the largest mining groups, so that there will always be a large custom refining business.

TANK HOUSE

Having decided upon the size of plant to be constructed, the next problem is the choice of the current density. This question has already been discussed at length in a previous article (CHEM. & MET. ENG., March 15, 1917), and in turn depends upon several primary factors such as cost of power, silver values, etc. It has also to be remembered that the plant will earn more on its investment when operated at a little higher density than that giving the lowest operating cost. For example, if a certain plant could treat its most economical tonnage of 100,000 tons a year for \$20 while by

FIG. 1. VARIATION OF COST WITH SIZE OF PLANT

raising the density proportionally it could treat 110,000 tons at \$20.30, 120,000 tons at \$21, with very little additional capital expenditure, and the refining toll was \$25 a ton, then the earnings on 100,000 tons would be \$500,000 a year, and on 110,000 tons \$517,000, but on 120,000 tons only \$480,000. On the other hand, it is generally wise to leave this margin for the growth of the business.

The density having been settled on, tank dimensions have next to be considered. In the earlier plants electrodes about 2 x 3 ft., twenty pairs to the tank, were used with densities around 15 amp. per sq. ft. This gave 3,600 amp. on a circuit, which was in those days a heavy amperage to rectify on a single commutator. Today thirty pairs of electrodes are used without material lowering of the current efficiency and in one plant electrodes 4 ft. square are in successful use, although 3 ft. square is a more popular size where soluble anodes are

employed. With thirty pairs of 3-ft. electrodes and the average density of 20 amp. per sq.ft. the current on a circuit becomes 10,800 amp., still well within the limits of the modern commutator. At an overall current and time efficiency of 85 per cent this current will produce 17,258 lb. of copper per tank per month, or 575 lb. per pair of electrodes.

The spacing center to center of anodes will lie between 4 and 4½ in., depending upon the purity of the bullion treated and the age of electrodes adopted. In general the column of liquor between anode and cathode should be about 1½ in. across. General practice as to the age ratios of electrodes is indicated in Fig. 2. At the lower densities cathodes and anodes are of identical age, while as the density rises increasing numbers of sets of cathodes are drawn during the life of one set of anodes. The weight of the anode can be obtained by multiplying the expected output per tank-day per pair of electrodes by the days' life determined upon and adding 15 per cent to this figure to allow for anode scrap. From the area and weight (allowing something for porosity) the thickness may be calculated, and this plus 2½ in. will give the anode spacing.

Having settled upon the output per tank-day, the total number of tanks required is at once obtained, and the next question to be considered is the number of independent circuits required. In general the voltage per tank will be somewhere between 0.30 and 0.45 volt. This figure depends upon many factors, the chief being the current density. An average value in practice would be 0.35 volt. To this must be added a sufficient allowance for liberator and stripper tanks. The former require about 2.2 volts when on normal work and 2.5 volts when used for complete removal of copper. Ordinary work would call for 2 per cent of the former and none of the latter, but this depends upon the analysis of the anodes to be handled. Stripper tanks are operated on a somewhat wider spacing than regular tanks, and this means fewer pairs of electrodes, higher current density and higher voltage—say 0.50 volt as compared with 0.35. If we take 80 per cent of the number of electrodes per tank, 24-hr. sheets, allow another 20 per cent for loops and bad production and 10-day cathodes, not forgetting that one stripper blank yields two starting sheets, each regular tank will demand the equivalent of three sheets a day, while each stripper tank will produce thirty-eight sheets a day.

POWER HOUSE

The general power problem will be reviewed in the last article of this series.¹ To this may be added, however, some notes on electrolytic switchboards.

Heavy direct currents are satisfactorily handled by multiblade knife switches with a duty of 50 amp. per sq.in. of sliding contact. Circuits are neither opened nor closed under load, but a circuit breaker with a no voltage release should be placed on each circuit, not as a protection to the generator, the armature resistance of which is too low to "short circuit," but to protect men and apparatus in the tank house. It is not uncommon to have an open circuit due to the crane drawing cathodes by mistake from a tank which has not been cut and heavy arcing may result. A bar or tool laid across lines where any considerable effective voltage is present is promptly "burned out." An automatic engine stop should also be provided in the case of reciprocating

engines, as with a sudden release of load due to the opening of the circuit breaker there is always a chance that the governor will act sluggishly, as the steady full load day after day gives it but little exercise.

Recording and integrating instruments are not of great value on the electrolytic switchboard, beyond giving a check on the employees, as hourly readings of the indicating instruments are ample for all records.

Several precautions are necessary in setting instruments on the board.² With voltmeters there is little trouble, though the same precautions must be taken with regard to the effect of stray field as stated below for ammeters. The very heavy currents met with in electrolytic work accentuate some causes of error which are ordinarily negligible in switchboard ammeters, and if a limiting error of 1 per cent is to be attained distribution of the current in the shunt, thermo-electric effects, switchboard temperature, magnetic effect of stray field on the instrument and possible dynamo action of the leads must be accounted for. Error of 1 per cent may be taken as the limit of accuracy of the best types of switchboard ammeters for heavy direct current.

Care should be taken to place both shunt and instrument in suitable positions when designing the switchboard. In the first place, the shunt should be obtained from the maker with short bars inserted in the slots

FIG. 2. GROWS OF CATHODES DURING LIFE OF ANODE

usually provided in the shunt terminals, these bars in turn to be bolted to the busbar carrying the current to be measured. In this way the shunt is calibrated with the same distribution of current through the various leaves, as will be the case in after use. It is practically impossible to disconnect a high-capacity shunt down to the slotted terminals and put it back in place again without altering the calibration more or less, due to change in the distribution of the contact resistance between main bar and shunt terminals, and consequent slight change in the amount of current carried by the different leaves of alloy. This, in turn, slightly affects the ratio between drop of potential between binding posts and total current carried. These changes in resistance are very small, but the total resistance of a good 5,000-amp. shunt is but about 0.00001 ohm. There is no way to detect the error introduced in this way except by calibration in place.

Unequal heating of the two shunt terminals will introduce a constant error from the thermo-electric junctions formed where the alloy leaves are soldered on to the copper blocks. This may easily amount to 1 per cent of the full-scale reading, may be either positive or nega-

¹Publication to follow shortly.

²Addicks, *Trans. Am. Electrochem. Soc.*, vol. 9, p. 239.

tive, and will show as a zero error on shutting down the circuit which will gradually disappear as the shunt cools off. Sometimes compensating devices are applied to avoid thermo-electric errors, but if the shunt is so placed in the busbar that the facilities for conducting away heat are approximately equal on both sides, there will be no appreciable error, and such devices should be unnecessary. The alloy leaves of a shunt would be red hot at full load were it not for the heat-dissipating qualities of the large copper terminals. There should be practically equal radiating surfaces of bus bar for 3 or 4 ft. each side of the shunt. If placed close to a switch on one side, there is sure to be a thermo-electric error in the shunt, as high capacity switches frequently run hot. The best plan is not to attempt to place the shunt back of the switchboard at all.

DANGER OF OVERHEATING SHUNT

The temperature at which a shunt runs will depend upon how heavily it is loaded and the opportunity afforded to dissipate the heat generated. The temperature indicated by a thermometer and well placed upon one of the terminal blocks should not be allowed to exceed 200 deg. F., owing to the danger of starting the solder and consequent failure. The temperature coefficient of the alloy used in the resistance leaves is generally so low that no correction to the instrument reading need be applied for the heating of the shunt.

A sensitive millivoltmeter is used to measure the drop. The condition for maximum sensitiveness would require that all of the resistance of the instrument be in the armature of the d'Arsonval type so generally used. And in order that a given resistance may afford as many ampere turns as possible without making too heavy a hobbin, the material must be one low in specific resistance, such as copper. The use of copper means a high temperature coefficient, and in order to keep within 1 per cent on large switchboard ammeters it is always necessary to correct for instrument temperatures. The largest size of instrument—dependent of capacity, as change of size for current rating is made in shunt and not in instrument—has a temperature coefficient corresponding to that of pure copper, or about 0.2 per cent per deg. F. The smaller types are lower in temperature coefficient, as the lighter movement gives the instrument designer more leeway. In high-resistance instruments, such as voltmeters, there is a series coil, made of low temperature coefficient alloy, which forms so large a proportion of the total instrument resistance that the coefficient of the whole is negligible.

STRAY FIELD

One of the most important sources of error is the magnetic effect of stray field in the immediate vicinity of a bar carrying several thousand amperes. Instruments should never be placed within 2 ft. of such bars. The iron shield usually provided is not only likely to be faulty as a filter for lines of force of such density, but consequent poles are formed in the case itself.

The magnet of an unscreened Weston portable instrument may be permanently altered by placing the meter too close to such a bar, and this is very easy to do especially in the tank house. Even at a distance of several feet the readings of a portable instrument are thrown out a division or two on the scale and where accuracy is desired the average of two readings with the instrument turned 180 deg. should be used.

The resistance of the leads on a switchboard ammeter is generally about 5 per cent of that of the instrument, and the screw connections must be kept clean. If it is found necessary to lengthen the leads, care must be taken that the resistance is kept constant by a proportionate increase in size of wire used. The leads should be twisted and kept from swinging loosely in the presence of stray field. Otherwise there is a dynamo action which the millivoltmeter is sensitive enough to indicate by a pulsating needle.

When several high-capacity ammeters are in use, it is advisable to have them interchangeable. The various instruments may then be checked at any time by connecting them to the same shunt. Connections should also be arranged, if possible, to put the shunts in series, when they too may be checked.

The question of proper section for busbars has been fully discussed in a previous article (CHEM. & MET. ENG., Nov. 15, 1916). No insulation is used and faced metal to metal joints without amalgam, tightly bolted together, are satisfactory at 200 amp. per sq.in. contact surface. Either rolled or cast bars may be employed. The bars from the switchboard to the tanks are best carried overhead and the positive and negative leads kept some distance apart.

FURNACES

For smooth operating there should be at least six furnaces, three anode and three wirebar units, two of each being in service and one out for repairs. For a capacity of 100,000 tons a year, and allowing for Sundays and holidays out, we should have 600 charges a year of 333,000 lb. each plus scrap, etc., which is a furnace of fair size, although it is possible to build them very much larger.

FIG. 2. FUEL RATIO OF FURNACES

The limit of size has been the ability to charge, refine and cast the charge in 24 hr. With hand charging and ladling, using the same men for both operations, 60,000 lb. is a large furnace. If a fresh crew is used for charging and as many ladlers employed as can be accommodated at the ladle door, 100,000 lb. can be reached. With hand charging but mechanical ladling, 300,000 lb. is

possible, using three charging doors. With full mechanical charging and ladling 500,000 lb. is easily reached, and using two charging and ladling machines even a larger capacity can be attained.

The fuel economy increases rapidly with the size of furnace as indicated by the curve in Fig. 3. Labor charges also fall up to the point of mere duplication of machine units. Repairs fall at first, but a very large furnace is likely to incur heavier repairs than one somewhat smaller. This is especially true where too great a span of roof is attempted. A refining furnace is subjected to much greater and more rapid temperature changes than an ore reverberatory.

Small silica furnaces produce excessive slag as they run hot and have an undue proportion of wall exposure. A 40,000-lb. silica furnace will form 4 or 5 per cent of slag on a wirebar charge, whereas a similar furnace of 150,000 lb. or over to the charge can be held down to half that amount. With basic side walls there is a substantial decrease in these figures, and with a full basic furnace operating on a charge of good quality the slag made can be held down to 0.5 per cent or better.

Altogether a furnace casting a charge of 300,000 lb. or more may be considered a thoroughly economical unit.

SILVER REFINERY

A 100,000-ton plant will call for a silver refining department of reasonable size. At 1.25 per cent slimes there would be four tons of slimes a day to treat, calling for a doré reverberatory of about twenty tons capacity, just the size of the first copper furnaces. It is desirable to use but a single furnace in order to hold at a minimum the large bottom absorption of values. A spare furnace may be held in reserve and in case of accident or at inventory time substituted, the first unit being completely dismantled at that time and its silver content recovered.

A very small plant can best sell its slimes to a lead refinery, but owing to the difficulty in getting a fair sample of such rich material this is not desirable when the tonnage is of any size. Small plants would use a cupel furnace and sulphuric acid parting, while reverberatory smelting followed by electrolytic parting is generally employed in large ones.

While the purifying system affords a suitable outlet for accumulations of sodium salts in the electrolyte, niter may be used to remove the copper from the slimes. Where closed cycle operation is undertaken the copper is generally oxidized by roasting. Either method gives good metallurgical results.

PURIFYING

The metallurgical principles upon which the choice of a purifying system must be based have been fully covered in a previous article (CHEM. & MET. ENG., June 15, 1917).

Where insoluble anode tanks are employed for the complete removal of the copper from batches of electrolyte, ample provision must be made for the very low current efficiency of these tanks. Should a bluestone plant be employed, the design will be based upon the quantity of shipping salt to be produced. The crystallizing tank space employed in different plants varies considerably. A fair average figure, making allowance for the recrystallization of fines, is 58 cu.ft. per short ton per month of marketable bluestone. When estimating the proportion of impurities removed from the electro-

lyte, it must be remembered that a large part of the copper in the bluestone comes from the shot towers and not from the electrolyte. For each 1,000 cu.ft. of crystallizing space, allowance should be made for, say, 175 cu.ft. shot towers, 375 cu.ft. shot tower receiving tanks, 225 cu.ft. slimes settling tanks, 250 cu.ft. boiling tanks, and 275 cu.ft. iron cementation tanks. These ratios, however, may be varied between rather wide limits to suit individual cases differing in analysis of electrolyte, character of shot, climate, etc.

GENERAL

Two main principles should be kept in mind in the program of operation of any plant. The first is that all the impurities possible should be eliminated at the anode furnaces, using basic furnaces if necessary. It is much more costly to throw this burden upon the tank house and silver refinery.

The second is to do everything possible to facilitate uniformity of operating conditions. As a general rule anodes of constant composition, a uniform current density and a single electrolyte should be used throughout the tank house.

Artificial Graphite

Graphite is manufactured by the Acheson Graphite Co. at Niagara Falls, N. Y. This company utilizes the electric power generated at the Falls to make graphite from anthracite coal or from petroleum coke. This product is used mainly in lubricants, but it is also used in paints, foundry facing, preventives of boiler scale, and fillers for batteries.

Artificial graphite may be used for any purpose for which natural graphite is employed, according to the United States Geological Survey, except in the manufacture of large crucibles. Patents have been issued recently, however, for methods of manufacturing crucibles in which artificial graphite may be used. Artificial graphite is peculiarly adapted to the manufacture of certain graphite products, among them graphite electrodes, which are not made from natural graphite and for which the demand has greatly increased in recent years. The table below, published by permission of the Acheson Graphite Co., represents only the manufactured graphite that comes into competition with natural graphite.

New Cold Process for Vulcanizing Rubber

It is reported that a very important discovery of a new process of vulcanizing rubber has been made by Prof. Peachey of the Manchester (England) College of Technology—important because it is a method of cold vulcanizing. It makes use of two gases, hydrogen sulphide and sulphur dioxide, which react on each other to produce water and free sulphur. The professor has found that when crude rubber, either in a solid form or in solution, is treated with these two gases the sulphur produced by their interaction vulcanizes the rubber. If the rubber is mixed with a waste material such as sawdust or leather scraps or paper, and the mixture is vulcanized, the resultant materials will serve a variety of useful purposes.

Properties and Constitution of Glues and Gelatines—V

A Study of Adhesive Properties—The Relation of Jell Strength to Shear Strength; of Jell Strength to Tensile Strength; of Viscosity, Melting Point, Origin of Stock, Joining Pressure and Prolonged Heating to Shear Strength*

By ROBERT H. ROGUE, PH.D.

THE criterion for the value of a glue as a joining agent must, in most cases, be the actual strength developed and maintained by that glue in service, and any method of grading whereby relative strengths are not truly expressed is pernicious and unscientific. Indeed, actual strength tests may be considered as the only absolutely dependable basis upon which to evaluate glues, and for some very particular purposes, as in the selection of glues for airplane service by the United States Forest Service,¹ such tests are consistently made upon all samples before approval. But, in general, strength tests are not made for several reasons. The machinery for making such tests is heavy and expensive. The time required is long—about seven days. The technique requires very careful and precise handling in order to obtain accurate results. Other methods of grading have long been in use, and are believed to be reasonably satisfactory. And, most important perhaps, the strength test itself has ever been more or less unsatisfactory, even in the hands of skilled research men. There are many elements concerned in the results obtainable besides the glue itself. There may be mentioned the hardness and uniformity of grain of wood, and its moisture content; the varying degree of perfection obtained in making the joint; the distribution of the pressure over the surface of the joint; the difficulty of duplicating the joining pressure exactly. These and many other less obvious factors all make for inexact, and not readily duplicatable, results.

NO STANDARD MECHANICAL STRENGTH TESTING METHOD

Again, many methods have been suggested in the literature for making the strength test, but there is as yet no generally accepted method which may be considered as standard. Rudeloff² used red beech wood, 185 mm. long, 125 mm. broad, 50 mm. thick, placed so that the glued surfaces crossed at right angles. They were later torn apart. A. H. Gill³ used maple blocks shaped like cement briquets, glued together endwise, and broken in cement-testing machines. He also made briquets of fullers earth, diatomaceous earth, quartz sand, and sawdust, but could not obtain consistent results. He then dipped strips of filter paper into glue solutions, and when dried broke them with the Mullen paper tester. His results by this method were more concordant. G. S. Hopp⁴ molds glue into strips, allows them to dry on tin or aluminum nets, machines down to dimensions desired, and pulls apart in torsion machine. He obtains the stretch and tensile strength, which vary from the average 1 to 3 per cent. The Forest Service

of the United States Department of Agriculture has developed a strength test⁵ which seemed somewhat more satisfactory than any of the others. Maple blocks are selected which have been carefully cured and are of uniform grain. These are 12 x 2½ x 1 in. They are carefully resurfaced, heated to 40 deg. C. and joined. After subjection to a uniform pressure for 24 hr., and allowed to stand seven days to dry out, these are sawed into blocks such that the area of the joint is exactly 4 sq.in. These are then broken by shearing the two blocks of wood apart. By taking averages of several tests, the results obtained are reasonably concordant.

Because of the unsatisfactory status of the strength test, and in order to determine specifically the relation between other properties of glues, and their strength in service, this series of experiments was undertaken. We will consider:

The Relation of Jell Strength to Shear Strength.

The Relation of Jell Strength to Tensile Strength.

The Relation of Viscosity to Shear Strength.

The Relation of Melting Point to Shear Strength.

The Relation of Origin of Stock to Shear Strength.

The Relation of Joining Pressure to Shear Strength.

The Effect of Prolonged Heating Upon Shear Strength.

THE RELATION OF JELL STRENGTH TO SHEAR STRENGTH

The method used in this, and in all of the other experiments in this paper, with the exception of that section upon tensile strength, was that described as adopted by the Forest Products Laboratory at Madison, Wis. The greatest of care was used in selecting only uniformly grained blocks, in obtaining a perfectly plane joining surface, and making the joint under exactly uniform conditions. The glue was dissolved in varying amounts of water, heated to about 65 deg., and applied to the wood, which was heated to about 40 deg. C. Four test blocks, each with a glued area 2 in. square, were cut from each of the larger glued blocks, and these were placed in a special shearing machine, of the type used by the Forest Products Laboratory, and pressure applied until they broke. The pressure reached and the condition of the fracture were noted.

In the first experiments the joints were pressed together in wooden clamps, care being used to produce as nearly equal pressures as possible on successive joints. The pressure obtained by these clamps was measured by a spring and deflectometer, and found to give a total of about 350 lb., or, as the area of the joint per clamp was about 13 sq.in., a pressure of about 27 lb. per sq.in. was obtained. Dilutions were made of from one part of glue to one and a half of water in the lowest grades up to one of glue to five parts of water in the highest. This was done in an attempt to

*For Parts I, II, III and IV, see *Chem. & Met. Eng.*, vol. 23, Nos. 1, 2, 3 and 4, July 7, 14, 21 and 28, 1920, pp. 5, 61, 105 and 154.

⁴*Ibid.*, vol. 12 (1920), p. 356.

⁵*Loc. cit.*

determine the concentration at which the maximum strength was developed. The glues used consisted of the standard grades from the highest to the lowest of both hide and the bone products. This means that glues with a regular variation in jell strength were used.

An examination of the data furnished from this series of experiments will reveal that although there is in general a decrease in strength with decrease in grade, yet this is by no means consistent. Many low-grade glues have an apparently greater strength than a much higher grade product, and vice versa. But even this feature does not remain in the leastwise constant at the slightly varying concentrations used. In fact, we must accept the conclusion that the results obtained are erratic and altogether undependable.

TABLE XLIV. SHEAR STRENGTH OF STANDARD GLUES AT VARYING CONCENTRATIONS

It occurred to the writer that, although care was used to obtain equal pressures upon all joints, it might be that such inequalities as did exist in the pressure of joining might be sufficient to account for the inconsistent results obtained. Experiments were therefore initiated which proved this to be the case. These will be described later.

The above experiment was therefore repeated, in part, by placing each set of blocks, after joining, between parallel plates in a torsion machine, and applying a pressure uniformly of 200 lb. to the sq.in. This pres-

TABLE XLV. SHEAR STRENGTH OF STANDARD GLUES, JOINED IN TORSION MACHINE

Joining pressure, 200 lb. per sq.in. Concentration, 1 to 2 $\frac{1}{2}$

Bone Glues							
Average strength per sq.in. 2,750	2,310	1,645	1,590	1,360	1,180	485	0
Per cent wood broken.....	25	0	0	0	0	0	0

sure was selected from the consideration, described hereafter, that at that pressure slight variations in pressure will have only a slight effect upon the strength of the joint, and also that the strength developed at this pressure is nearly a maximum. Only one concentration was used, e.g., one part of glue to two and a half parts of water.

The results were this time satisfactory in that in every case (except one) the strength of the joint varies directly as the grade, or jell strength. The cause of the one exception was at first not understood, but has since been satisfactorily accounted for, and will later be discussed. The maximum strengths were not in every case measured, due to the fact that in the highest grade

glues, the glue was stronger than the wood, but by noting the relative percentage of the several fractures which occurred in the wood instead of in the glued joint, our conclusions are relatively satisfactory, and entirely dependable.

Other series were tested with the object of eliminating any possible effect which the viscosity might have upon the strength of the joint. Glues were selected which were of uniform viscosity but of varying jell strength, and tested as before. The results so obtained

TABLE XLVI. RELATION OF JELL STRENGTH TO SHEAR STRENGTH

Joining pressure, 200 lb. per sq.in. Concentration, 1 to 2 $\frac{1}{2}$			
Jell strength.....	H ₂	H ₄ +	H ₄ -
Viscosity (capillary tube).....	50	50	50
Average strength per sq.in.....	2,670	2,300	1,850
Per cent wood broken.....	65	8	0

corroborate the data of the previous experiments, that the strength of a glue in service is a function of the jell strength, and this irrespective of the viscosity. Table XLVI will illustrate this point.

THE RELATION OF JELL STRENGTH TO TENSILE STRENGTH

It seemed desirable to obtain, if possible, a shearing in which the break would occur entirely within the joint, and not in the wood. It seemed possible that if joints were made and sawed so that they might be pulled apart, the jaws of the torsion machine might hold the fibers of the wood so tightly that they could not slip before the glue at the joint gave way. Accordingly, blocks were joined and sawed into sections 6 x 1 in. and the joint cut to an area of 4 sq.in. The standard glues were used at a concentration of 1 to 2 $\frac{1}{2}$.

TABLE XLVII. TENSILE STRENGTH OF STANDARD GLUES Pressed in clamps. Concentration, 1 to 2 $\frac{1}{2}$

Hide glues.....							
	H ₁	H ₂	H ₃	H ₄	H ₅	H ₆	...
Average strength per sq.in.....	540	345	318	340	304	290	...
Per cent wood broken.....	75	25	50	25	0	0	...
Bone glues.....							
	B ₁	B ₂	B ₃	B ₄	B ₅	B ₆	B ₉
Average strength per sq.in.....	435	390	385	295	230	210	130
Per cent wood broken.....	25	30	0	0	0	0	0

The desired effect was not, however, produced, as, on pulling apart, the fibers of the highest grade glues slipped through the jaws of the machine. This method did, however, confirm the results obtained by the other method, and placed the order of strength exactly as had been previously obtained. It is noticeable that the pull necessary to break the joint is small in comparison with the push necessary to shear the blocks apart by the other method. As this method had no advantages over the former one, and some disadvantages, it was not used in any further tests.

THE RELATION OF VISCOSITY TO SHEAR STRENGTH

The actual significance of viscosity in the evaluation of a glue has been a point upon which there has been much diversity of opinion. It is most commonly stated, however, that viscosity is a measure of the water-taking capacity of the glue, which means that a glue with high viscosity may be worked at a greater dilution, and therefore at greater economy, than another one, similar in all respects, except of low viscosity. Indeed, A. H. Gill¹ came to the conclusion that "tensile strength, jelly test and viscosity bear no relation to each other." These

¹Loc. cit.

conclusions were undoubtedly reached through an insufficiency of data, and failure to eliminate all but one variable in any given set of experiments. The author has shown that the strength of a glue is a function of the jell strength, and, in general, the viscosity varies as the jell strength, but a set of glues might easily be selected which would vary regularly in viscosity, but the curve of jell strength might be a zigzag. In this case the strength of the glues, being influenced by jell strength, would probably also be irregular.

Accordingly, groups of glues were selected which

FIG. 22. RELATION OF VISCOSITY TO JELL STRENGTH. HIDE GLUES

were throughout of the same jell strength, and divided into sub-groups, representing varying viscosities. Joints were made with these in the manner already described. The concentration was one part of glue to two and one-half parts of water. They were uniformly subjected to a joining pressure of 200 lb. per sq.in.

TABLE XLVIII. RELATION OF VISCOSITY TO SHEAR STRENGTH.

Jell strength.....	H ₃	H ₂	H ₁
Viscosity (MacMichael 140 deg. F.).....	36	28	24
Strength per sq. in.....	2,640	2,330	2,275
Per cent wood broken.....	30	6	0

The data show that in all cases the strength of the joint is greater with the high viscosity glues, and decreases regularly as the viscosity.

THE RELATION OF MELTING POINT TO SHEAR STRENGTH

It has been demonstrated that the strength of a glue in service is a function both of the jell strength and of the viscosity. Were we to consider jell strength as the measure of strength, then, although probably three-quarters of all glues would be correctly evaluated, yet the remaining quarter, due to an abnormally high or an abnormally low viscosity, would be either stronger or weaker than the grade they were assigned to represent. And if we considered viscosity (as usually taken at 140 deg. F.) as the measure of strength, the same reasoning would assign an even greater proportion of glues to grades which were not indicative of their true strength value.

The writer has shown previously¹ that both the jell strength and the viscosity are functions of the melting point. He has also shown that if we take the viscosities at regularly decreasing temperatures the viscosity curve will gradually merge into the jell strength curve. It is, therefore, evident that there must be a curve intermediate between that of the viscosity at 140 deg. F. and the jell strength which will represent more accurately than any other the exact relative value of all glues. This is obviously the melting point curve. It has also been shown that, since the viscosity curve and the jell strength curve merge into one another as the temperature is lowered or raised, a measurement of viscosity at low temperature serves admirably as a measure of melting point.

We are now, therefore, in a position to state with assurance that the strength of a glue is normally always proportional to its melting point, and that the melting-point method of evaluation is inevitably superior in accuracy of grading, with strength in service as the criterion, to either a jell strength or viscosity (at 140 deg. F.) method.

We find that this conclusion explains many points which were otherwise not understood. It has been noted that the order of strength in glues H₁ and H₂ was reversed from what we had expected. But a melting-point determination reveals that in this case H₁ is the higher, and should, therefore, be expected to have a greater strength. Apparent abnormalities in many other glues are similarly accounted for.

In order to determine the exact nature of this

FIG. 23. RELATION OF VISCOSITY TO JELL STRENGTH. BONE GLUES

melting-point strength curve about 300 measurements were made on all grades of glues.² Measurements were made at temperatures of 140, 100 and 90 deg. F. A remarkably lengthened curve is obtained at 90 deg. F., of such a nature that there is a difference in the reading of from 5 to 25 points between any two grades. This makes the precise allocation of any glue an easy matter, and not subject to improper grading due to trifling

¹See p. 64.

²See p. 66 for details and method.

variations in technique. The curve at 90 deg. F., or about 32 deg. C., is therefore recommended as the most suitable temperature for the melting-point determination. At lower temperatures many glues would be difficult to handle, and their melting-point curve would doubtless have been drawn too close to their jell-strength curve to serve the end of obtaining the most accurate evaluation.

TABLE XLIX. AVERAGE VISCOSITY (MACMICHAEL) OF ALL GLUES AT 140, 100 AND 90 DEG. F.

	Capillary Tube Viscosity 140 deg. F.	MacMichael Viscosity 140 deg. F.	MacMichael Viscosity 100 deg. F.	MacMichael Viscosity 90 deg. F.
H ₁	53	36	60	100
H ₂	50	30	46	76
H ₃	49	25	44	58
H ₄	48	20	32	43

H ₆	47	20	27	35
H ₇	44	14	21	27
B ₁	49	27	47	79
B ₂	47	22	38	53
B ₃	46	19	29	38
B ₄	45	14	22	26
B ₅	44	13	21	25
B ₆	44	11	17	21
B ₇	43	8	12	13

A summary of the data is given in Table XLIX and the curves are shown in Figs. 22 and 23.

THE RELATION OF ORIGIN OF STOCK TO SHEAR STRENGTH

It seemed very desirable to know if the nature of the origin of the stock used in the manufacture of glue might affect the strength of the product in some way that might not be revealed by the customary tests of

FIG. 24. EFFECT OF JOINING PRESSURE UPON STRENGTH

jell strength or viscosity. Accordingly, glues were selected as follows: Series C consisted of glues of uniform test and produced from similar stock. Series D consisted of glues of uniform test but each group made from different types of stock. Series E consisted of glues of varying test and obtained from similar stock. Tests were made in the usual manner, at a concentration of one part of glue to two and a half parts of water, and joined at a pressure of 200 lb. per sq.in.

The results obtained do not reveal any variation in strength with the type of stock used which is not

similarly revealed by the measurements of jell strength and viscosity. In series C the strength of the three sets are practically identical, as would be expected from their uniform test and similar origin. In series D the jell strength is nearly constant, but the nature of the stock varies, and the viscosity varies. The strength is found to vary as the viscosity. In series E the

FIG. 25. EFFECT OF HEATING A HIGH-GRADE GLUE IN SOLUTION UPON STRENGTH

strength is found to vary as the jell strength and viscosity, which run parallel, regardless of the fact that the glues are derived from similar stock. So it seems

TABLE L. INFLUENCE OF ORIGIN OF STOCK UPON STRENGTH

Joining pressure 200 lb. per sq. in. Concentration 1 to 2½			
Series C: Uniform test; similar stock:			
Jell strength.....	H ₃	H ₂	H ₃
Viscosity (capillary tube 140 deg. F.)....	51	51	51
Strength per sq.in.	2,260	2,325	2,280
Series D: Uniform test; different stock:			
Jell strength.....	H ₂	H ₂	H ₂
Viscosity.....	53	52	51
Strength per sq.in.	2,900	2,710	2,440
Series E: Varying test; similar stock:			
Jell strength.....	H ₃	H ₂	H ₂
Viscosity.....	53	52	46
Strength per sq.in.	2,720	2,155	1,690

that a consideration of the jell strength and viscosity, or the melting point, will correctly establish the value of the product with reference to strength, regardless of the origin of the stock.

THE RELATION OF JOINING PRESSURE TO SHEAR STRENGTH

As soon as it became evident that slight variations in the pressure at which the blocks were joined produced a decided variation in the strength of the joint, experiments were started to establish exactly the relation which existed between the joining pressure and the strength of the joint. A medium-grade hide glue and a medium-grade bone glue were used. They were made up to a concentration of one part of glue to two and a half parts of water, and on joining subjected to pressures of from 10 to 1,400 lb. per sq.in. This was accomplished by pressing between the parallel plates of a torsion machine.

The data obtained, when plotted, reveal curves which show the strength to increase very rapidly with increase in joining pressure up to about 200 lb. per sq.in. Beyond this point the strength continues to increase gradually up to 1,000 lb. per sq.in. The hide glue had here obtained nearly the strength of the wood. On increasing the joining pressure of the bone glue beyond this point no further strength was developed, but it remained constant to 1,400 lb. per sq.in. It is at once evident that if maximum strength is desired a high pressure should be used—certainly not less than 200 lb. to the sq.in. And not less important it should be pointed out that a low-grade glue at a high pressure may be made to do the work and produce joints of as great strength as a high-grade product at a low pressure.

TABLE LI. EFFECT OF JOINING PRESSURE UPON STRENGTH.
Concentration, 1 to 24.

Joining Pressure.	10	25	50	100	150	200	300	500	700	1,000	1,400
Glue H ₂	1,965	2,080	2,160	2,520	2,615	2,660	2,700	2,785	2,860	3,030	
Glue B ₂	885	...	1,255	1,435	1,675	...	1,845	1,845

A summary of the data is given in Table LI, and the curves are shown in Fig. 24.

THE EFFECT OF PROLONGED HEATING UPON SHEAR STRENGTH

Some joiners are in the habit of buying the highest grades of glue and heating them in solution for some time before using. This process is known to lower the viscosity and the jell strength, but it results in increased tackiness and the joiners who practice this method claim they can produce stronger joints than by any other procedure. In order to ascertain if heating could actually produce a stronger product, in spite of its apparent contradiction to theory, the highest grade glue was subjected to heating at about 80 deg. C. for periods of 2, 4, 8 and 12 hr. The concentration was one part of glue to two and a half parts of water. The joining pressure was 200 lb. per sq.in.

The data show the strength of the glue to decrease regularly as the period of heating, and when plotted show nearly a straight line. This conclusion agrees with results obtained by Linder and Frost,² who find that a heating at 150 deg. F. for 20 hr. produces a loss in strength of 30 to 45 per cent. Our data show that in 2 hr. the strength has dropped from H₂ to the equivalent of H₁; in 4 hr. to H₂; in 8 hr. to H₃; and in 12 hr. to H₄. This experiment affords conclusive proof that the heating of a glue produces a distinct and very appreciable loss in strength, and that this loss in strength is proportional to the period of heating.

Temperature, 80 deg. C.	Joining pressure, 200 lb. per sq. in.	Conc., 1 to 24			
Hours heated.....	0	2	4	8	12
Viscosity (MacMichael 140 deg. F.)	220	105	68	54	50
Strength per sq. in.	2,940	2,785	2,515	2,145	1,965

The averages are given in Table LII and the curve is shown in Fig. 25.

SUMMARY OF RESULTS

The following conclusions may be drawn from the several experiments described in this paper:

The strength of a glue in service is a function of the jell strength.

The strength of a glue is a function of the viscosity. The strength of a glue is directly proportional to the melting point.

The melting-point method for evaluation of glues by the process described is recommended as yielding a true index of actual strength in service.

Variations in the origin and type of stock used in the manufacture of glue produces no variations in the strength of the product which are not made manifest by jell strength, viscosity, or melting-point determinations.

The strength of a glued joint varies directly as the joining pressure applied, up to about 1,000 lb. per sq.in. Below 200 lb. to the sq.in. the variation is large. Above that the variation is small.

The strength of a glue decreases regularly as the period of heating in solution.

The method of testing the strength of glued joints as developed by the Forest Products Laboratory at Madison, Wis., is recommended to scientific workers as one which, with careful technique, will give satisfactory results.

New Jelly Product From Grape Juice Waste

As a result of the increased use of grape juice particularly since prohibition went into force, a new product has been developed from the waste material left after the expulsion of grape juice. This waste product, called pomace, is composed of the skins and pulp and can be made into a fine jelly.

The United States Department of Agriculture, in co-operation with the large grape juice producers in the state of New York, have made experiments with this material, which show that a jelly comparable in cost with apple jelly can be made. In addition the seeds may easily be separated and an edible oil made from them.

Legal Notes

BY WELLINGTON GUSTIN

Establishing the Market Value of a Product—The Damages to a Purchaser for Resale

Judgment for George O. Seward against the Pennsylvania Salt Manufacturing Co. has been reversed by the Supreme Court of Pennsylvania and a new trial awarded. The suit was one for damages for an alleged breach of contract in the purchase of hydrate alumina. The salt company is located at Natrona, Pa., and Seward is a metallurgical engineer of New York. The latter sought to purchase the chemical product for use during 1916, and the company offered to furnish him 100 tons a month from March to December, inclusive, 1916, at 4c. per lb. f.o.b. Natrona, net cash, offer open until November, 1915. On Nov. 11, 1915, Seward wrote the company accepting the offer of 100 tons monthly.

The company requested the name of the buyer so that contracts might be written up, etc. Seward did not reply to this request, and on Jan. 22, 1916, the company again wrote that as it had heard nothing from him since its request, it assumed his plans had not developed as anticipated and therefore the matter was considered a "dead" issue, but Seward replied that the matter was not a "dead" issue and that he would send shipping instructions before March 1, for the 100 tons to be delivered to him during March.

COMPANY REFUSES TO DELIVER

The shipping instructions were given, but the company refused to deliver the specified hydrate alumina or any part thereof and set up as a defense that the offer to sell was made upon the faith of an express parol agreement that Seward was to organize a new company for the manufacture of aluminum by which all of the chemical products should be used and none resold, and that otherwise the offer would not have been made.

It was admitted that no new company was organized nor was the product required in Seward's business. Correspondence between the parties referred to companies in which he was interested and to a proposed new company. But this constituted no agreement as alleged by the salt company. To establish that parol evidence was introduced and largely relied upon. The jury found for Seward and the court awarded him \$34,500.

DIFFICULT TO ASSESS DAMAGES

Upon the appeal the important question was that of damages. The Supreme Court stated several important rules that should be here repeated. The general rule is that in an action for failure to deliver goods according to sales contract the measure of damages is the difference between the contract price and the market value at the time and place of delivery, with interest [2 Sedgwick on Damages (9th Ed.) par. 734]; and plaintiff may recover such damages without having supplied his wants elsewhere. The trial judge so instructed the jury, but the difficulty in this case was the lack of evidence of market value. The only proof as to that was the amount for which Seward contracted to resell 25 tons of the March delivery, and the price at which the company supplied its other customers during the months in question. Those sales were individual

transactions in small amounts and not made in the open market, and not sufficient to establish the market value, especially of such quantities, said the court.

Hydrate alumina is manufactured at other chemical works, but there was no evidence as to price for which it there sold, or as to its general selling price in open market. It may not at all times be possible to establish a general selling price, and in such cases actual market value may be shown by proof of facts and circumstances fixing to a reasonable degree of certainty the amount the product would bring if offered at ordinary sale.

NO MARKET VALUE FOR HYDRATE ALUMINA

Again, where a product is not obtainable in the open market a plaintiff could recover his actual damages by proving such damages through showing that he required the products in his business, that he procured them elsewhere, or made them, at a cost greater than the contract price. In this case Seward proved no such actual damages. In his behalf it might be urged that he could have resold the hydrate alumina at a profit. But, said the court, how can it be determined that an article without market value can be resold at a profit? The chances thereof are too speculative to form the basis of a recovery. (106 Pa., 237.) Moreover, the anticipated profits on a resale are not recoverable unless in contemplation of the parties when the original contract was made, and here they were not. (26 L.R.A., N.S., 1,191.)

Therefore, unless the proof shows the subject of the contract had a market value, and that greater than the contract price at the time of delivery, so as to bring the case within the general rule above stated, the buyer can recover only nominal damages.

The judgment against the salt company was reversed because the lower court erred in treating the evidence as sufficient to justify a finding of market value, which it was not.

Debtor's Check Not Payment Until Check Is Paid

Payment by check was the subject of a recent decision where plaintiff had sued for the agreed value of goods sold defendant. On appeal the Supreme Court said that a check of the debtor in liquidation of his own debt is not payment until paid, unless in some very special case such check was taken in absolute extinguishment of the debt—which case can hardly be supposed.

The acceptance of buyer's check by sellers did not constitute payment, where no payment had been made on check, and this is true although the sellers had previously accepted buyer's checks as payment when checks were paid; the only inference, if any, from such practice being that tender of check would prevent the sellers from asserting a default by reason of non-payment or non-tender.

If for any reason the seller failed to deposit the buyer's check, such buyer is bound to keep his tender of payment good, and when sued to pay the money into court. Further, the court said, the mere fact that the sellers of goods, under agreement giving the buyer a right to certain discount upon payment within a certain time, permitted the buyer to deduct the discount on two or three occasions when payment was not made within the time of the credit did not give the buyer a right to such deduction in all subsequent transactions.

Molybdate: Its Occurrence, Detection and Determination in Partly Oxidized Molybdenite Ores

A Review on the Composition of Molybdate Ore, Its Occurrence and Concentration—Chemical Test for Molybdate in the Presence of Molybdenite—Outline of Methods for Qualitative and Quantitative Analysis

By J. P. BONARDI*

THERE are several oxidized molybdenum minerals found in the United States,¹ but none are of commercial importance at the present time except molybdate ($\text{Fe}_2\text{O}_3 \cdot 3\text{MoO}_3 \cdot 7\frac{1}{2}\text{H}_2\text{O}$), which commonly occurs with molybdenite as an alteration product and the recovery of which is difficult by the flotation process of ore dressing in use for the sulphide mineral. Oil flotation has proved so successful, especially on low-grade disseminated molybdenite (MoS_2) ores assaying below 0.5 per cent Mo, that it is being used almost exclusively for making high-grade concentrates. Molybdenum in the form of the oxide is unrecoverable by the ordinary flotation processes adopted for the recovery of the sulphide mineral; consequently, it tends to go to waste along with the tailings. The seriousness of this loss can be judged when it is known that one of the largest molybdenite orebodies in this country, situated at Climax, Col., carries from 10 to 20 per cent of the molybdenum content in the form of the above-mentioned oxide mineral.

It is said that the flotation mill at Climax for treating the crude ore has at present a capacity of 1,000 tons a day; and at this rate of production the ore reserves already developed in this ore deposit alone insure steady operation for more than thirty years. The importance, then, of recovering the molybdate mineral should not be overlooked or underestimated. The application of sodium sulphide (Na_2S) to a flotation charge under the proper conditions has resulted in recovering a considerable part of the oxide mineral. One of the chief difficulties in a sulphidizing treatment is the fact that molybdic oxide is readily soluble in an alkaline solution, so that the sulphidizing treatment must be carried out in as near a neutral solution as is possible. Molybdenum can, however, be recovered from an alkaline solution by adding CaCl_2 until causticity has been neutralized, followed by vigorous boiling.² The determination, then, of the oxide mineral becomes an important factor in metallurgical calculations, especially so if the relative floatability of each mineral is desired. A search through the literature revealed the fact that no methods were given for the determination of molybdate in molybdenum minerals.

Besides the large known deposit at Climax, it is commonly the case to find that oxidation of the molybdenite on the outcrops of such veins has resulted in the formation of considerable molybdate. Usually it disappears entirely at depth, excepting the case at Climax, where it occurs practically throughout the orebody at present

blocked out. The oxidation is still prominent down to 350 ft. below the surface.³

Horton,⁴ in speaking of molybdate, states:

"Molybdate is a hydrous ferric molybdate ($\text{Fe}_2\text{O}_3 \cdot 3\text{MoO}_3 \cdot 7\frac{1}{2}\text{H}_2\text{O}$) and theoretically contains 39.63 per cent of molybdenum. . . . It is an alteration of molybdic acid (liberated by the oxidation of the molybdenite) and limonite. The formation of the limonite in many cases may have resulted from the weathering of pyrite which is commonly associated with the molybdenite, simultaneously with or previous to the weathering of the molybdenite.

"For many years the erroneous idea has existed that molybdate agrees in composition with the artificial molybdic trioxide obtained by oxidizing molybdenite. The present textbooks on mineralogy almost universally persist in this error, giving the composition of molybdate as MoO_3 , and stating that the pure mineral contains 66.7 per cent of molybdenum. That such is not the case was first called to the author's attention by chemical tests of a sample of molybdate which from microscopic examination seemed to be practically pure. The presence of a large percentage of iron was determined, and the same results obtained from tests on other samples of molybdate from different localities led the author to believe that the iron was an essential part of the mineral. Schaller⁵ had not only proved the presence of combined iron in molybdate but had definitely established its composition as $\text{Fe}_2\text{O}_3 \cdot 3\text{MoO}_3 \cdot 7\frac{1}{2}\text{H}_2\text{O}$."

TESTS FOR MOLYBDITE

Regarding tests for molybdate, Schaller⁵ writes:

"On heating the mineral in a closed tube abundant water is easily given off and the mineral assumes a dark-olive color. On further heating it again becomes lighter in color. On heating the mineral in a crucible the color changes are very marked. At first the yellow mineral darkens and becomes a dark gray, then it becomes a light yellow, and on further heating changes to a deep orange color. If the mineral now be allowed to cool, the orange changes to yellow and back to orange again on reheating. If the dark-colored material be allowed to cool, it retains its dark gray color and on reheating passes through yellow to the orange. On heating for some time at a higher temperature, the mineral, on cooling, becomes a permanent bright green. By further heating all the molybdenum is volatilized and the dark-red ferric oxide remains. The mineral is readily soluble

in hydrochloric acid and is decomposed by ammonia. After awhile, all the molybdenum goes into solution, leaving the insoluble ferric hydroxide."

QUALITATIVE AND QUANTITATIVE TESTS FOR MOLYBDITE IN THE PRESENCE OF MOLYBDENITE

The following chemical test for molybdite in presence of molybdenite has been tried out in the laboratory of the Golden Station of the U. S. Bureau of Mines, and has proved reliable for detecting molybdenum down to 0.01 per cent molybdenum on the basis of a 1-g. sample. A complete solution away from the sulphide mineral can be effectively made by one of the three following reagents: A 10 per cent solution of hydrochloric acid, a 10 per cent solution of ammonium hydroxide, or by a 5 to 10 per cent solution of sodium carbonate. The ore is ground fine, placed in an Erlenmeyer flask, 200 c.c. of water added and then enough of one of the above reagents to make a 10 per cent solution. This is then boiled for thirty minutes, filtered and washed. Before filtering the HCl solution it is made first ammoniacal to precipitate out the bulk of the iron. Any of these three methods of solution will completely dissolve the oxide of molybdenum in a boiling solution without affecting the sulphide to the least extent. This has been thoroughly tried out and has always given reliable results. Pure molybdenite was given the same treatment, but none was found in solution in any of the three cases.

The filtered solution of any one of the above filtrates is then tested for molybdenum by the thiocyanate test as follows: The filtrate if alkaline is acidified with HCl and some H₂O, added to oxidize any reduced iron or molybdenum that might have passed through into the filtrate. This is boiled to drive off most of the excess H₂O, and is then made ammoniacal. If any iron hydroxide separates out, filter and wash. To the filtrate, which is now free from iron, aluminum and silica, make acid with HCl, add some ammonium or potassium thiocyanate and immediately follow by zinc. If any molybdenum is present, a bright cherry-red color will develop which will disappear only on standing for a prolonged period, depending upon the amount of molybdenum present in the solution to be reduced. If hydrogen peroxide is added to the solution after the cherry-red color has developed, the color disappears, but will return as soon as the peroxide has been reduced. This color reaction with thiocyanate is very definite and certain, but if the mistake is made by adding the zinc first, which reduces the molybdenum, and then later followed by the thiocyanate, scarcely any color will be developed. When only traces or small amounts of molybdenum are present, a concentration of the cherry-red color can be obtained if the solution is shaken with a small volume of ether, when any color in the liquid will be extracted by the ether and intensified as a golden brown in the ether rings that form at the top of the liquid on standing. The thiocyanate color produced when iron is present in solution soon changes colorless, by the addition of zinc, usually before the cherry-red color of the molybdenum starts to develop."

Weigh 5 to 10 grams of the finely pulverized molybdenite ore into a 400 c.c. Erlenmeyer flask. Add 200 c.c. water and then one of the following: 20 c.c. strong

ammonia, 20 c.c. concentrated HCl, or 15 g. Na₂CO₃, and boil vigorously for 30 min. Wash the sides of the flask down with water, filter and wash. To the filtrate, if alkaline digestion was made, add HCl to acid, followed by a few c.c. of hydrogen peroxide and boil. Hydrogen peroxide is also added to the HCl filtrate; this oxidizes the iron which might have been carried in solution in a reduced condition. Next, add ammonia in excess and heat. If any precipitate settles out—consisting of iron, alumina and silica—filter and wash. If large in amount, dissolve in HCl and reprecipitate, wash and filter. The molybdenum now in the form of soluble molybdate should have a volume of approximately 350 c.c. Make the solution acid with HCl, using methyl orange as an indicator, adding about 5 c.c. excess of acid. Add 5 to 10 g. ammonium acetate—enough to decompose the free mineral acid—and 2 to 5 c.c. of acetic acid. The solution is next heated to boiling and precipitation of the molybdenum is now made in the hot solution by titrating the molybdenum content in the solution with a lead acetate solution (about 18 g. crystallized lead acetate per liter) added slowly from a burette until a test drop taken from the solution gives no color change with a drop of freshly made tannic acid solution (about 0.10 g. dissolved in 20 c.c. of water) used as an outside indicator. The disappearance of the brown color indicates when all the molybdenum has been removed from solution by precipitation. Next add 2 or 3 c.c. excess of the lead acetate solution and place the beaker back on the hot-plate and keep at or near the boiling point until the precipitate has crystallized and settled.

When settled, filter hot and wash well with hot water; if precipitate is bulky, wash with a 2 to 3 per cent solution of ammonium acetate. The washed filter is placed in a fireclay annealing cup and ignited at a dull red heat. After complete ignition of the paper, cool and weigh directly. The weight of the PbMoO₄ times 0.2615 gives the weight of the molybdenum in the precipitate, from which the percentage can be calculated.

The size of the sample taken for an analysis should be chosen if possible as not containing over 0.15 g. molybdenum (equivalent to 0.25 g. MoS₂), since above this amount the precipitated lead molybdate will be too bulky to handle to the best advantage. Hydrogen peroxide can not be added in the digestion of the sample along with the alkali or acid, since in combination with these reagents a chemical action will take place on the sulphide mineral, molybdenite, and render it appreciably soluble. A large excess of lead acetate should be avoided.

The following results are typical of an analysis carried out as outlined, showing the comparison of results as obtained by the three methods on the same sample of partly oxidized molybdenite ore containing a total of 5.2 per cent molybdenum, the molybdenum content being distributed in approximately the ratio of 1:1 between molybdite and molybdenite mineral.

Wt. of Sample, Grains	Treatment - 1 Hr. of Boiling	Wt. PbMoO ₄	Per Cent Mo
5	200 c.c. H ₂ O + 10 g. Na ₂ CO ₃	0.4820	2.52
5	200 c.c. H ₂ O + 25 c.c. HCl	0.4770	2.49
5	200 c.c. H ₂ O + 30 c.c. NH ₄ OH	0.4800	2.51

The writer wishes to acknowledge the assistance rendered by Max Shapiro in conducting a series of analyses and to Dr. S. C. Lind, superintendent of the Golden station, who has made many valuable suggestions.

Three samples of pure molybdenite, on the same treatments, gave no test for molybdenum in the filtrates. Golden, Col.

Synopsis of Recent Chemical & Metallurgical Literature

Resistance of Silk and Linen Fabrics to Weather Conditions and Ultraviolet Rays.—To determine the influence of changes in weather conditions and of ultraviolet rays on silk and linen fabrics, LEO VIGNON has conducted a series of experiments, the results of which he presented before the French Academy of Sciences (*Compte Rendus*, May 31, 1920, pp. 1,322-1,324).

The influence of changes in weather has been studied by submitting bands of silk and linen fabric (0.2 m. x 0.05 m.) during June and July, to these conditions:

(a) Sunlight. Bands stretched on wooden frames covered with window glass were exposed vertically to the sun's rays in a dry place from 10 a.m. to 4 p.m. for 45 consecutive days.

(b) Dry Heat. Bands dried for 20 min. at 100 deg. C. were quickly placed in a bottle containing dry calcium chloride and closed hermetically. The bottle was then kept heated in a drying stove to 60-65 deg. C. for 3 hr. per day for 45 consecutive days; during the remainder of each day the bottle was kept at atmospheric temperature and not submitted to the sun.

(c) Wet Heat. The test was similar to that for dry heat but instead of calcium chloride, the bottle contained a few c.c. of water.

(d) Moisture and Sunlight. Bands placed in a large bottle containing a little water were exposed to the sun from 12 noon to 6 p.m. for 45 consecutive days.

(e) Moisture and Diffused Light. The bottle containing the bands as in the previous test was kept in a closed place out of the sun for 45 consecutive days.

The results obtained are tabulated in Tables I and II.

TABLE I. ACTION OF THE WEATHER ON SILK FABRICS

Test	Resistance to Tearing kg. per M. Average			Decrease per Cent	Final Aspect of the Fabrics
Fabric used	1900	1920	1910		Grayish white
(a) Dry sunlight	1580	1600	1590	20	White
(b) Dry heat	1900		1900	0.5	No change
(c) Wet heat	1660	1680	1670	13	Somewhat yellowish
(d) Moisture and sunlight	1360		1360	30	Green and black moldiness, no color
(e) Moisture and diffused light	1740	1760	1750	9	White moldiness, color

TABLE II. ACTION OF THE WEATHER ON LINEN FABRICS

Test	Resistance to Tearing kg. per M. Average			Decrease per Cent	Final Aspect of the Fabrics
Fabric used	1540	1560	1550		Grayish white
(a) Dry sunlight	1280	1300	1290	20	White
(b) Dry heat	1380		1380	12	No change
(c) Wet heat	1300-1340		1320	15	Somewhat yellowish
(d) Moisture and sunlight	1060	1100	1080	31	No change
(e) Moisture and diffused light	440-560		500	68	Abundant green and white moldiness, strong odor

The influence of ultraviolet rays has been studied with 0.17 m. x 0.05 m. bands placed at a distance of 0.1 m. from a Heraeus lamp. To eliminate the action of the ozone which is formed around the lamp the tests were performed near an open window to have an atmosphere with small quantities of ozone. The temperature

of the band was around 25 deg. C. The results obtained are given in Table III.

TABLE III. ACTION OF ULTRAVIOLET RAYS ON SILK AND LINEN FABRICS

Fabrics	Silk Resistance to Tearing, kg. per M.	Decrease, per Cent	Linen Resistance to Tearing, kg. per M.	Decrease per Cent
Before exposure	1,600		1,800	
After 24-hr. exposure (0.1 m. from lamp)	1,300	20	580	68
Before exposure	1,540		1,780	
After 48-hr. exposure (0.1 m. from lamp)	925	40	Below 200	Above 89
Before exposure	1,520		1,780	
After 96-hr. exposure (0.1 m. from lamp)	817	48	Below 200	Above 89
Before exposure	1,660		1,840	
After 72 hr. exposure (0.3 m. from lamp)	1,470	17	1,520	18

The conclusions arrived at are that fabrics of animal origin (silk) are more resistant than those of vegetable origin (linen) to the influences of weather and ultraviolet rays. This can be explained by the fact that albuminoid molecules resist hydrolysis better than the cellulose molecules.

Elutriation Tests of American Kaolins.—The May, 1920, issue of the *Journal of the American Ceramic Society* prints an original paper by H. G. SCHURECHT of the Bureau of Mines on this important subject.

The classification of clays according to grain size is important because many physical properties are to a limited degree functions of the size of grain. A more complete knowledge of the fineness of grain of our domestic kaolins would be valuable in determining American substitutes for foreign clays. The paper contains a complete record of the tests with tables. Chemical analyses, microscopic examination, sieve analyses, and elutriation or washing analyses were all carried out, and determinations were made as to relation between velocity of flow and diameter of particles. Tap water was compared with distilled water in the elutriation tests. The writer sums up the results of his extensive work as follows:

The elutriation of kaolins should be carried on with distilled water instead of tap water, as the soluble salts in tap water cause the clay particles to coagulate and settle as larger grains.

The residue in each can should be thoroughly stirred each day to overcome the error due to settling of fine particles on the sides of the cone. This may be done by stopping the water flow and gently blowing air through the stem of the thistle tubes. Each sample should be elutriated for at least three days to insure a complete separation or until the overflow from the last can is clear.

Results check more closely when the residues are stirred at intervals and when distilled water is used in place of tap water.

The clays should be deflocculated and fed into the elutriator drop by drop, and during this period the velocity of the flow should remain about one-third below maximum.

It was found that the Georgia, South Carolina and Pennsylvania kaolins tested in this investigation contain a high per cent of clay-like substance below 0.010 mm., comparing favorably with the English china clay in this respect.

The North Carolina kaolins tested showed a comparatively low per cent of fine or clay-like substance.

English ball clay contains an extremely high per cent of fine material, 98.55 per cent being carried away by a flow of 0.0197 mm. per sec. Only 40.75 per cent of English kaolin was carried off by this velocity. It is evident that the greater plasticity and bonding strength of ball clays, as compared to kaolins, is due largely to their finer grains.

The observed diameters of the particles, as separated with distilled water, correspond reasonably closely to the calculated results obtained by using Schone's empirical formula.

Properties and Uses of Lime.—General Information of interest to chemists and chemical engineers on the properties and uses of lime will be found in the second edition of Bureau of Standards Circular 30.

Lime is made by heating limestone under certain conditions, whereby it is decomposed into an escaping gas, carbon dioxide, and a non-volatile residue, lime or quicklime. This lime, when treated with water, hydrates, or slakes. If water is used in great excess, a paste results; but if the amount is properly regulated, the hydration yields a dry powder, which is called hydrated lime. Since natural limestones contain more or less magnesia, iron, silica, etc., the quality of the lime will depend to some extent upon the nature and amount of these foreign materials. It will also depend upon the way in which the stone is burned.

As a material for building construction, hydrated lime is better adapted than quicklime because it eliminates the labor usually required to do the slaking. It is used very largely as a brick mortar, as an ingredient in concrete, and in the scratch and brown coats of plaster. A particular grade of hydrated lime, noted for its plasticity, is sold as finishing lime and is used for the white coat of plaster.

Limestone, quicklime, and hydrated lime are used to a large extent as chemical reagents in the manufacture of other materials. In some of these industries the quality of the lime is of minor importance. In others, the use of only one of the three forms of lime is satisfactory, and the quantity and kind of impurity which the lime may contain is definitely specified.

Eighteen of the most important chemical industries that use lime are enumerated. Brief descriptions of these industries are given, showing why and how they use lime, and the quality of lime which they require.

A list of the tests of lime which are usually made includes chemical analysis, rate of hydration, plasticity, sand carrying capacity, time of set, compressive strength, proportion of waste, and fineness.

Inks.—The Bureau of Standards has recently issued Circular 95, giving general information on the subject of inks. The composition and manufacture are discussed only briefly, but the methods of testing which are in use at the Bureau of Standards are given in sufficient detail to enable any chemist to use them. After a brief introduction on the history of ink, there are discussions of writing and copying inks, ink tablets and powders, marking, canceling, stamping, duplicating and sympathetic inks. The methods used for the laboratory examination of all but the last of these kinds of ink are next taken up. Under the analysis of writing inks, for instance, are the following headings: Total solids, ash, iron, sulphuric anhydride, tannin, dye, chromium, penetration, fluidity, keeping quality and resistance to light and reagents. For the other kinds of ink there is not such a variety of tests necessary. The circular closes with a short bibliography.

Recent Chemical & Metallurgical Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Removal of Sodium Sulphate From Solutions.—Sodium sulphate may be removed from solutions which are saturated or nearly saturated in respect to this salt by treating with a quantity of calcium sulphate sufficient to form the double salt $\text{CaSO}_4 \cdot \text{Na}_2\text{SO}_4$, commonly known as glauberite. The double salt is removed by filtration and digested with sufficient water to break it up into a mixture of solid CaSO_4 and a solution of Na_2SO_4 . (1,343,443; F. A. FREETH, of Sandiway, and H. E. COCKSEGE, of London, England; June 15, 1920.)

Chrome Alum.—Ferrochrome when ground to a fine powder dissolves in sulphuric acid, the solution being complete in two to three days when working on a manufacturing scale. The presence of lead accelerates the solution of the ferrochrome. The resulting solution is treated with potassium chloride or sulphate and the chrome alum crystallized out. Prior to the addition of the potassium salt, the iron content of the solution may be reduced about one-half by crystallizing out ferrous sulphate. (1,343,725; GUSTAF H. HULTMAN, of Stockholm, Sweden; June 15, 1920.)

Manganese Dioxide Depolarizer.—When manganese carbonate (prepared by the interaction of solutions of manganese sulphate and sodium carbonate) is subjected to an oxidizing roast at 325 to 425 deg. C., manganese dioxide is formed according to the equation:

This reaction is accelerated by the presence of chlorides or chlorine containing materials in the roast. Thus the addition of $\frac{1}{4}$ to 8 per cent sodium chloride greatly decreases the time and temperature required for roasting. (1,343,390; HAROLD C. CHAPIN, of Cleveland, Ohio, assignor to National Carbon Co.; June 15, 1920.)

Ammonium Perchlorate From Sodium Perchlorate and Ammonium Sulphate.—A nucleus solution is prepared at 100 deg. C. to contain 12.2 per cent ammonium perchlorate, 6 per cent sodium perchlorate and 15.5 per cent sodium sulphate. To this solution is then added the proper amounts of sodium perchlorate and ammonium sulphate, to produce a solution containing 32.5 per cent ammonium perchlorate, 5.5 per cent sodium perchlorate and 12 per cent sodium sulphate, and the anhydrous sodium sulphate which separates at this temperature is removed. The filtrate is diluted with a quantity of water so that, when cooled to 20 deg. C., the resulting solution will contain 11.7 per cent ammonium perchlorate, 6.8 per cent sodium perchlorate and 14.9 per cent sodium sulphate. The solution is then cooled to the above-mentioned temperature and the pure ammonium perchlorate removed. The mother liquid from the ammonium perchlorate is concentrated by evaporation until it has the same concentration of dissolved salts as the original nucleus solution. (1,342,956; GUY C. GIVEN, HOWARD S. MCQUAID and RALPH A. LONG of Tamaqua, Pa., assignors to Atlas Powder Co.; June 8, 1920.)

Removal of Nickel From Zinc Sulphate Solutions.—H. L. SULMAN and SAMUEL FIELD, of London, England, first remove by usual methods such metals electro-negative to zinc as iron, arsenic, antimony, copper and cadmium; this solution freed from these metals is treated with finely divided zinc dust at a temperature of 80 to 100 deg. C. The nickel remaining in solution after this treatment is less than one part per million. (1,341,601; assigned to the Metals Extraction Corp., Ltd.; May 25, 1920.)

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Effecting Reactions at High Pressure and at High Temperatures.—In carrying out reactions at high temperatures—for example, the synthesis of ammonia—it is necessary to protect the outer pressure-sustaining wall of the apparatus—for example, by interposing a layer of liquid, such as fused potash-soda mixture—that is stable, inert and a poor conductor of heat. According to the present invention, movement of the liquid such as would vitiate its protective action is prevented by a fitting consisting of a pile of rings of a material that is a poor conductor of heat and has the property of removing any hydrogen, if this is one of the reacting-gases, dissolved by the liquid; such a material is magnetic oxide of iron. (Br. Pat. 140,083—1919. L'AIR LIQUIDE, SOC. ANON. POUR L'ETUDE ET L'EXPLOITATION DES PROCÉDÉS. G. CLAUDE, Paris, May 12, 1920.)

Catalytic Apparatus for Ammonia.—In apparatus for effecting exothermic reactions in gases, the latter are led to a mass of catalyst through a tube which also serves to convey electric current into the apparatus for starting or promoting the reaction; preferably, the tube itself acts as the heating element and it may also serve as a heat interchanger between the products of the reaction and the incoming gas. The invention relates particularly to apparatus for use in the synthesis of ammonia. In the apparatus shown, the reaction tube *T*, containing the catalyst, is enclosed in a pressure-sustaining tube *T'*, and the latter is protected by molten material in which is immersed heat-insulating material. The reaction gases are led in through the tube *t* which forms the heating-element and is provided with a series of bars to support the catalyst and with earthenware or china disks *D* to obviate short-circuiting; the gases pass through the whole length of the tube and escape through an opening *O* at its lower end. In the free space above the catalyst the tube is coiled to provide a heat interchanger, and to prevent undue rise in temperature this part of the tube is thicker and of a better conductor, or the spirals are short-circuited. In use, a heavy

CATALYTIC APPARATUS
FOR AMMONIA

current of low voltage is passed through the tube in order to produce a temperature gradient between the reaction-tube and the outer wall *T* comparable with that obtaining during the normal working of the apparatus; by this, the protective material is fused regularly, and overdue strains on the tube *T* are obviated. (Br. Pat. 140,089—1919. L'AIR LIQUIDE, SOC. ANON. POUR L'ETUDE ET L'EXPLOITATION DES PROCÉDÉS. G. CLAUDE, Paris, May 12, 1920.)

Tanning.—To accelerate tanning processes, compressed or liquid air, or oxygen in a more or less compressed state, is brought into contact with the hides. The hides to be tanned are placed in closed pits into which there is admitted either pure water or water containing tanning substances and air or oxygen compressed more or less strongly according to the nature of the hides. The closed pits containing the hides may be supplied from a central pit, the liquid being in constant circulation and, if necessary, filtered on leaving the central pit. (Br. Pat. 140,092—1919. TANNAGE RATIONNEL MEURANT, SOC. ANON., Liège, Belgium, May 12, 1920.)

Electrolytic Production of Alcohols, Glycols, Ethers, Hydrocarbons and Oxygen.—Aldehyde or paraldehyde, derived from acetylene, is electrolytically reduced to alcohol or ethyl acetate. An acid electrolyte is employed, such as sulphuric acid of 5 to 10 per cent strength, or a solution of sodium bisulphate, phosphoric acid or an organic sulphonic acid. If a mercury compound is added, acetylene may be passed directly into the liquid instead of being separately converted into aldehyde. In the production of alcohol, anode oxidation is prevented by a diaphragm, but for ethyl acetate, the diaphragm is omitted or an inefficient one employed. The cathode may be of lead, pure or antimoniated, and optionally amalgamated or electroplated with lead; or a body of mercury may be used. Suitable materials for the anode are platinum, lead, oxide of iron, carbon and graphite. The last two impart an agreeable bouquet to the alcohol. When alcohol is to be produced, a cathode density of 2 to 3 amp. per sq.dm. is employed, and the temperature is not allowed to rise much above 40 deg. C. About 10 per cent of aldehyde is initially added to the electrolyte; a subsequent addition may raise the proportion of organic substance above 30 per cent. If the temperature, concentration of acid or aldehyde, current density, or duration of treatment is increased, byproducts are obtained, such as 1 to 3 butane-diol, crotonyl alcohol, butyl alcohol, and ethyl ether. Catalytic dehydration of the first or second of these gives butadiene. Oxygen, with or without ozone, is evolved at the anode, and may be utilized for metal-working, purification of waste waters and sewage, or oxidation of nitrous vapors. (Br. Pat. 140,115—1919. P. V. H. PASCAL, Angoulême, France, May 12, 1920. See also Pat. 148,527—1919, May 19, 1920.)

Catalytic Hydrogenation.—An aluminate of a heavy metal such as nickel is used as the catalyst in the hydrogenation of unsaturated organic compounds such as fatty acids and their esters. The catalyst is prepared, for example, by mixing solutions of nickel sulphate and sodium aluminate, washing the precipitated nickel aluminate, and afterward treating the dried aluminate at a temperature of 300 to 400 deg. C. with a current of hydrogen. The aluminate may be precipitated in an inert carrier such as kieselguhr. (Br. Pat. 140,371—1919. NORDISKE FABRIKER DE-NO-FA. AKTIESELSKAP, Christiania, May 12, 1920.)

Third Meeting, International Union of Pure and Applied Chemistry

THE third meeting of the International Union of Pure and Applied Chemistry was held in Rome June 22 to 25, under the presidency of Prof. Charles Moureu, member of the Institut de France. There were present representatives of Belgium, France, Great Britain, Italy and the United States, the five countries which founded the Union. (See CHEM & MET., vol. 21, pp. 234, 424.) Seven new countries were admitted unanimously; they are: Canada, Denmark, Spain, Greece, Holland, Poland and Czechoslovakia.

The following were the delegates to the general assembly:

For Belgium: Frédéric Swarts, professor at the University of Gand, and Dr. René Lucion, former president of the Société de Chimie de Belgique.

For Denmark: Einar Billman, professor of chemistry of the University of Copenhagen, and M. Warming.

For France: Prof. G. Bertrand, president of the Société Chimique de France; F. Bordas, professor at the Collège de France; Jean Gérard, general secretary of the Union Internationale de la Chimie; Paul Kestner, president of the Société de Chimie Industrielle; Prof. L. Lindet, member of the Institut de France; Ch. Lormand, chemist at the French Department of Agriculture; Camille Matignon, professor at the Collège de France, vice-president of the Société de Chimie Industrielle; Ch. Marie, general secretary of the Société de Chimie Physique; Prof. Charles Moureu, president of the Union Internationale de la Chimie, and M. Nicolardot, of the Paris Ecole Polytechnique.

For Great Britain: Sir William Pope, professor at Cambridge University, president of the Society of Chemical Industry, and Mr. Hay, technical delegate of the Reparation Commission.

For Greece: M. Zenghelis, professor at the University of Athens.

For Italy: G. Bruni, professor at the Polytechnic of Milan; Senator C. Ciamician, professor at the University of Bologna, president of the Associazione Italiana di Chimica generale ed applicata; F. Garelli, professor at the Polytechnic of Turin; R. Nasini, professor at the University of Pisa; L. Parodi-Delfino, vice-president of the Associazione Italiana di Chimica generale ed applicata; G. Oddo, professor at the University of Palermo; M. Plancher, professor at the University of Parma; Senator E. Paterno, professor at the University of Rome, president of the Consiglio Nazionale di Chimica; F. Quartieri, administrator of the Società Italiana Prodotti Esplosivi, and A. Peratoner, professor at the University of Rome.

For Holland: R. H. Kruyt, professor of physical chemistry at the University of Utrecht, president of the Nederlandsche Chemische Vereeniging.

For Poland: M. Kowalski, professor at the Polytechnic of Warsaw.

For Czechoslovakia: E. Votocek, professor at the Polytechnic of Prague, president of the Bohemian Chemical Society.

For the United States: Dr. Charles L. Parsons, general secretary of the American Chemical Society.

The meeting took place at the Corsini Palace, Accademia Nazionale dei Lincei.

Mr. Nicolardot spoke on the needs for standardizing the methods of chemical analyses for foods and proposed

the establishment at Paris of a permanent international bureau with this aim in view.

Mr. Crismer presented the report on the creation of an international institute of chemical standards. It was voted to organize such a bureau, which shall comprise three divisions, namely: chemical standards, standards for pure products used in research work, and standards for technical products.

Mr. Matignon read a report on the importance of thermochemical data and proposed the creation of a commission composed of specialists of the different countries, members of the Union, to prepare and submit a project for the establishment of thermochemical standards.

Mr. Trincheri spoke on the juridic value of sealed letters in the applications for patents, and the following motion was adopted after lengthy discussion:

The International Union of Pure and Applied Chemistry shall constitute a commission composed of members competent in the technical and juridic aspects of the problems relating to patents, and the first problems to be studied shall be the juridic value of the sealed letters and the creation of an international patent.

It was also voted that Italy shall prepare the project for such an organization.

INTERNATIONAL COMMISSION OF ATOMIC WEIGHTS CREATED

The study of the report of W. D. Bancroft, chairman of the Division of Chemistry and Chemical Technology of the U. S. National Research Council, on the International Commission of Atomic Weights, resulted in the creation of an international commission of atomic weights. The members proposed for this commission are Messrs. Clarke, Thorpe and Urbain.

Prof. Oddo presented a motion that the revision of the table of atomic weights shall be decennial and to take the atomic weight H = 1 as the basis of the system.

Mr. Marie made the motion that the International Committee of the Tables of Constants shall be included in the Union. This was approved.

To make the work of the conference more useful and to attract the attention of the respective governments on the importance of the work of the Union, the following motion was adopted at the request of the Danish delegation:

The International Union of Pure and Applied Chemistry hopes that all the delegates of the nations members of the Union will try to have their countries recognize the work of the Union as of public utility.

The Union will present to the Italian Government the proceedings of the conference *in extenso* with the request that they shall be communicated officially to the governments of all the participating countries.

In closing the meeting it was decided to accept the invitation of the Polish Government to hold the 1921 meeting in Warsaw.

Laboratory for Low Temperature Work to Be Established

A cryogenic laboratory is to be established at once in Washington in connection with the helium work being done by the Bureau of Mines. The necessary funds for equipping the laboratory and conducting the work are being allotted to the Bureau of Mines from appropriations made to the Army and Navy Departments. The work in this new laboratory will be directed by R. B. Moore, the chief chemist of the Bureau of Mines.

Current Events

in the Chemical and Metallurgical Industries

Dye Division of the American Chemical Society

The Dye Division of the A. C. S., which had its inception first as a Dye Symposium, then as a Dye Section, is now a duly organized part of the American Chemical Society. The division is undertaking to carry on regular and systematic work for the benefit of the dye industry of America in general, and the users of dyes, manufacturers of dyes, and dye chemists in particular, laying, of course, especial emphasis upon the chemistry of dyes and dyeing.

It is the duty and the privilege of every chemist in America who is interested in the chemistry, manufacture or use of dyes to enroll himself as a member of the American Chemical Society and of its Dye Division, to attend and to participate in the semi-annual meetings. The advantage will be mutual, both to the members and to the industry.

It is planned, as soon as funds permit, to compile and distribute a directory of dye chemists who are registered in the Dye Division of the A. C. S. Further information may be obtained from the secretary, R. Norris Shreve, 43 Fifth Ave., New York City.

High-Grade Silica for Los Angeles

Another forward step has been taken by southern California ceramic interests in the opening of the new \$100,000 plant of the Western Silica Co. at 2300 East 52d St., Los Angeles. With an initial output of thirty-five tons of washed silica per day, an amount which will soon be increased, this plant assures the development of the large deposits of high-grade silica in Antelope Valley, and assures for the industry a local supply of a product which has formerly had to be shipped from Illinois to the Coast. The silica from portions of these deposits runs over 99 per cent in purity, and is suitable for the highest grade of glass and ceramics. Charles E. Kaltenbach of Newark, N. J., a well-known silk goods manufacturer, is backing the new company, and Telfair Creighton is superintendent.

American Concern to Manufacture Ichthyol

The drug ammonium sulpho-ichthyolate, manufactured by the Meadows Oil & Chemical Corp. from an American fossiliferous marine deposit, is soon to appear on the market. Its germicidal action against *Staphylococcus py. au.* and *B. coli* is identical with the German product, but its penetration, particularly in high dilution, is from 200 to 400 per cent greater, and its therapeutic value has been found to be far superior.

Holyoke Mills Close for Repairs

The annual shut-down of the Holyoke mills began Saturday, July 31. The closing period was five days for the paper mills, and ten days for the balance of the factories. This closing is for the purpose of making necessary repairs to the canals. The paper mills will hardly regard it as an unmixed evil at this time, as it will enable them to accumulate at least a small reserve of pulp.

Importance of Italy's Water Power

Samuel M. Vauclain, president of the Baldwin Locomotive Co., on returning from a long business trip through Europe, declared that conditions in the countries he had visited were quite different from what is generally believed in America, and the rapidity with which those countries return to normal conditions would be according to the credit which they are able to obtain from abroad.

Conditions in Italy are better than in other countries. In fact, Italians are already producing and selling their products. If they could get better railway transportation they might even increase their export business, but they are handicapped by the lack of coal.

Despite this, however, due to its hydro-electric developments, Italy possesses some industries which can compete with the most important of those nations more favorably situated.

Several prominent manufacturers, realizing the seriousness of the coal situation, have rapidly substituted hydro-electric power. Among them was the Fiat Motor Works, which obtained control of the Mont Cenis Hydraulic Power Co. and can now generate 200,000,000 kw. throughout the year.

It is interesting also to note that the Italian Government has taken steps to electrify more than 6,000 km. of railway so as to reduce to a minimum the use of coal. Heat power being substituted by water power, coal consumption will be reduced by more than one-third. Thus in the very near future, when Italy will be able to utilize all the water resources so lavishly provided by nature, she will have solved one of the hardest problems which most European nations are now facing with great anxiety.

New Pulp and Paper Mill for Fort William, Ontario

Preliminary work has just begun on the plant for the new pulp and paper mill in Fort William, Ont. Its name is the Fort William Pulp & Paper Co. (Ltd.). It is said that the plant will cost about \$3,000,000, and when in full operation will employ 1,000 men and turn out approximately 100 tons of pulp daily. The raw product will be obtained from the nearby forests, and the necessary power will come from Kakabeka Falls, about twenty miles distant.

Judgment Affirmed Against Chemical Companies

In the two actions brought by Joseph and Catherine Stellwagon against the S. Wander & Sons' Chemical Co., Inc., the Appellate Division of the New York Supreme Court, Fourth Department, has affirmed judgment against the Chemical company.

In the case of the Walker M. Levett Co. against the British Aluminum Co. judgment for the former was appealed from by the latter, but the Appellate Division of the New York Supreme Court has affirmed judgment against the Aluminum company.

Organization Plan of the Federal Power Commission

The plan of organization of the Federal Power Commission was worked out at a meeting of the commission in Washington July 27. The work of the commission is to be divided into the following activities: Engineering, accounting, statistical, regulatory, licensing, legal, operation. The engineering division is regarded as the most important, as it must make: General investigation of the electric power industry; general investigation of water-power sites and estimates on cost of development; estimates of amount and value of power available at Government dams; examinations, cost estimates and reports to Congress on projects recommended for construction by the United States; examinations and reports to Congress on projects for which it is recommended that the cost of navigation facilities be supplied in whole or in part by the United States; preparation of plans for development of streams and stream systems upon which applications for licenses are made; construction plans proposed by licensees; physical valuation of properties in rate-making proceedings and when existing plants are brought under the act; determination of necessary repairs required for maintaining projects in effective operating condition; determination of adequate depreciation reserves upon properties; determination of operating rules necessary for protection of life, health and property.

The immediate direction of the engineering activities will be under the engineer officer, who will act as chief engineer of the commission.

For convenience in administering the act the country has been divided into five districts. The headquarters of these districts will be in Washington, St. Paul, St. Louis, Denver and San Francisco. Branch offices will be maintained in each of those cities at which notifications may be made and announcements given out.

Interstate Commerce Commission Issues New Coal Order

The issuance of a second New England coal order by the Interstate Commerce Commission, which repeals order No. 6, issued June 19, is expected to relieve the coal shortage in that section of the country. The experience with the former order enabled the operators and the railroads to determine accurately just what had to be done to move the tonnage necessary to insure an adequate supply for the northeastern group of states.

The new order places a single agent in charge of all tidewater facilities at Hampton Roads. The exact tonnage which must be moved each month is allotted to each of the tidewater railroads serving coal fields.

The railroads promise to supply sufficient cars at all mines assisting in furnishing the New England tonnage, to make maximum production possible. If this is done there will be enough coal left after the New England allotment is furnished to supply their other customers.

There is no disputing that the President two weeks ago was seriously considering the appointment of a Fuel Administrator and the restoration of governmental control over the coal industry. The harmonious way in which the operators and the carriers worked out the plan provided in the new New England order is said to have satisfied the White House that the situation will be met.

Factors Contributing to Anhydrous Ammonia Shortage

Despite some improvement in the transportation situation the shortage of anhydrous ammonia remains acute. Additional information gathered by Government specialists shows that the following factors are contributing to this shortage: The increased demand for anhydrous ammonia for refrigeration purposes; overproduction of ammonia cylinders; diversion of some of the ammonia liquor to make ammonium sulphate; the coal strike, which cut down the production of ammonia liquor; the switchmen's strike, with its resulting embargoes, which has caused slow movement to the consumer and has delayed the return of cylinders for refilling.

An important factor in increasing the amount of refrigeration at this time is the unusually large amount of meat which is being held in storage. Europe is producing more meat and other food products. This has enabled the Europeans to diversify their diet and the consequence is smaller purchases of American meat. A great deal of South American meat has been brought in and it, too, must be held in storage.

Following the armistice many coking plants closed, which reduced the production of ammonia liquor. Production was curtailed further by the influence exerted by the action of the Government in throwing 100,000 tons of ammonium sulphate on the market. It will be recalled that ammonium sulphate sold for pre-war prices for six months after the signing of the armistice. The farmers of both this country and England, however, had been educated during the war to use ammonium sulphate instead of sodium nitrate for fertilizing. This contributed largely to the rapid increase in the demand for sulphate. The attractive prices for sulphate are thought to have stimulated the making of sulphate in preference to anhydrous ammonia. It appears that the situation was not anticipated and sufficient retorts are not available for the liming of sulphate and the consequent production of anhydrous ammonia.

Artificial Silk Plant to Be Erected Near Buffalo

The du Pont Fibersilk Co., a company recently incorporated for the manufacture of artificial silk, has purchased a plant site of 100 acres on the shores of the Niagara River. The factory is to have 200,000 sq.ft. floor space and will employ about 700 persons. Active work on the plant is expected to commence some time in the spring.

This company was formed as the result of an agreement between E. I. du Pont de Nemours & Co. and the Comptoir des Textiles Artificiel of Paris, France, a company which controls practically all of the largest artificial silk plants of Europe.

Decision Delayed as to Site of Non-Metals Experiment Station

Matters have arisen which will delay the final decision as to the location of the non-metals experiment station of the Bureau of Mines. Dorsey A. Lyon, the Bureau's supervisor of stations; and R. B. Moore, its chief chemist, have submitted a report to Dr. Cottrell, the director of the Bureau, setting forth the advantages and the disadvantages of each of the localities under consideration. It may be that Dr. Cottrell will visit some of the proposed sites before making his decision.

Papers to Be Read at T.A.P.P.I. Meeting

In addition to the program published in our issue of July 28, page 167, the following papers of technical interest will be read and discussed:

Quick Method of Determining the Presence of Sulphate Fiber in Paper, by R. E. Lofton and H. F. Merritt.

New Felt Cleaning Device as a Means of Increasing Production, by C. A. Woodcock.

Boiler Room Efficiency Increased by a new Mercury Boiler, by W. L. R. Emmett.

A Continuous Mixing System for Newsprint Mills, by C. N. Allen.

Automatic Cooking Control for Sulphite Digesters, by E. J. Trimbe.

Preliminary Report for a New Method of Testing Lime and Cement Bags, by P. L. Houston.

Curtailing Bleach Consumption by Adding Sulphur to Digester Liquor, by George K. Spence.

Discussion of Substitutes for Alum and Rosin in Sizing Papers, led by W. E. Byron Baker and Max Cline.

It is of the utmost importance that the chairman of the local committee of arrangements, Charles F. Rhodes, International Paper Co., Glens Falls, N. Y., be notified, by means of reply postal cards sent previously, of members' intention to attend the fall meeting, it being necessary to arrange in advance for transportation for mill visitations, as well as luncheons, dinners, etc.

Members are again reminded of the necessity of making individual requests for room accommodations at hotel headquarters, Grand Union Hotel, Saratoga Springs, N. Y.

New Cold-Storage Plant at Liverpool

Consul Horace Lee Washington reports from Liverpool, England, that a cold-storage plant, claimed to be the largest and most up to date in Europe, is nearing completion at the Alexandria Dock, Liverpool, constructed by the Union Cold Storage Co. The first section of the plant, opened in August last, has a capacity sufficient for the storage of 11,000 tons of foodstuffs. When completed the total cubic capacity will be over 3,000,000 ft. and the accommodation will approximate 30,000 tons of eatables, including meat, fish, poultry, game, eggs, butter and cheese. The equipment will be the most modern obtainable. In order to avoid exposure of meat in transport from ship to the plant the adjacent dock sheds have been fitted with a system of conveyors which enables the meat to be picked up at any point and conveyed under direct cover to the plant, thus avoiding any break in refrigeration. The building is in direct railway communication with the main railway systems of the country.

New Lubricant Company

The Graphite Oils Co. (Ltd.) recently offered for public subscription 150,000 shares of £1 each to take over the going concern called Graphite Oils (Ltd.), of Glasgow. Fifty thousand shares (making the total capital £200,000) were issued in part payment of the purchase price to the vendor company.

According to the prospectus, the vendor company was established in 1913 to test and develop the discovery of a method for the manufacture of lubricating oils and greases with natural graphite in suspension therein. The uses of graphite as a lubricant, the prospectus remarks, were formerly limited, "because the engineer

could not find a means whereby it could be held in suspension in oil, and so could be carried with the oil into the internal workings of engines and bearings," but the process employed by the company has now rendered this possible.

Book Reviews

NON-TECHNICAL CHATS ON IRON AND STEEL AND THEIR APPLICATION TO MODERN INDUSTRY.

By *Le Vergne W. Spring*, chief chemist and metallurgist of the Crane Co., Chicago. New York: Frederick A. Stokes Co. 358 pp., 294 illustrations and diagrams.

This book is a collection of articles by Mr. Spring which appeared in the Crane Co.'s house organ called the *Valve World*, so arranged as to give a comprehensive series of popular talks on iron and steel from a scientific standpoint. It is interesting from cover to cover; written in an entertaining and agreeable style, and contains a great deal of information that the user of steel and the intelligent layman should know.

The work properly begins with an early history of iron; then the raw materials are considered, then the blast furnace, and following this comes a chapter called "A General Glimpse Ahead." This has less to do with the future development of the industry than with a survey of the many varieties of iron and steel now known and in use. It is a glimpse ahead for a pig of iron.

It is fair to say that the science of ferrometallurgy, as representative of the organization and arrangement of particles in ferrous alloys, is still too undeveloped to make explanations or even guessing easy. For this reason, and with no reflections on Mr. Spring, we wish the book were better than it is. We haven't got beyond the stage of rather messy thinking in regard to the philosophy of iron and steel, and we can hardly expect to get out of it until we know more than we do. What is most needed is research in pure chemistry without any thought of utilities. Here is a great field.

The author is not speculative and he does not point out what may be done at some future date. It is feared that with the death of Joseph E. Johnson, Jr., a great deal of valuable research on the behavior of iron ore when smelted with oxygen in the place of air has been lost. It is known that too much iron vaporized in his tests, but he believed that he was on the road to illuminating information and possibly to marked economies, but, as he told the reviewer a few weeks before he was run over and killed by an automobile, he was "not yet ready" to publish.

After Mr. Spring's "Glimpse Ahead" there follow chapters on Wrought Iron, Cementation and Crucible Steels, Bessemer Steel, Open-Hearth Process, Cast Iron, Malleable Cast Iron, Alloy Steels, High-Speed Steels, Mechanical Treatments, Rolling, Rolling Rods, Wire and Wire Drawing, Pipe and Tubes, Seamless Steel Tubes and Transformations and Structures of the Steels. This last was a hard chapter, and, considering the little real information that we have in comparison to the sum total yet to be discovered, it was well done. The book closes with an equilibrium diagram of iron-carbon alloys.

In treating such a big subject within a limited space it is possible, of course, to think up a great variety of important features of the subject that might have been treated which are either merely mentioned or that have not been discussed at all. But on the whole I think Mr. Spring is to be congratulated on writing in popular form (which takes more space by far than technical writing) a great deal of useful information in relation to his subject. An intelligent foreman in a machine shop, a steel mill or a foundry is likely to be a more intelligent foreman after he has read it.

ELLWOOD HENDRICK.

Personal

HOWARD C. ADAMS, formerly chief estimator for Tate-Jones & Co., Inc., has joined the George J. Hagan Co. of Pittsburgh, as engineer in its liquid fuel department.

CHARLES H. BREED, until recently metallurgist with the Brown Cork & Seal Co., of Baltimore, has joined the staff of Daniel M. Luehrs, industrial consulting engineer, Cleveland, Ohio, as consulting metallurgist in charge of the metallurgical laboratories.

EDWARD B. ELLICOTT, recently Colonel in the Chemical Warfare Service, has become associated with A. M. Castle & Co., iron and steel merchants, Chicago, in the capacity of chief engineer.

Dr. CHARLES H. FULTON, professor of metallurgy of the Case School of Applied Science, has resigned to become head of the department of mining engineering at the Missouri School of Mines, Rolla, Mo.

LLOYD HALL has accepted a position with the Boyer Chemical Laboratory Co. as research chemist in charge. He was formerly connected with the Chemical Warfare Service.

E. H. HEUMANN, until recently connected with the chemical department of the Crown Cork & Seal Co., Baltimore, Md., has joined the staff of Daniel M. Luehrs, industrial consulting engineer, Cleveland, Ohio, as chemist in charge of the chemical laboratories.

EUGENE F. HICKSON has resigned his position as first assistant chemist in the paint and varnish section of the Bureau of Standards to accept a position as associate engineer in the department of technical control of the American Writing Paper Co., Holyoke, Mass.

WALTER R. KIRNER is now associated with the synthetic chemistry department of the Eastman Kodak Co.'s research laboratory. Mr. Kirner was Lieutenant in the Chemical Warfare Service.

L. D. LE FORGE of the Bureau of Chemistry, Department of Agriculture, gave a talk recently before the Chicago Chemists' Club on corn-cob products. He exhibited some samples of paper, glue, woodstuffs and cellulose made from corn-cobs. He is co-operating with the Forest Products Laboratory, Madison, Wis., on paper manufacture.

Dr. R. B. MOORE, chief chemist of the Bureau of Mines, is in Golden, Col., assisting in the winding up of the affairs of the Bureau of Mines station, which is to be moved to Reno. Before his return to Washington he will visit Reno and the United States helium laboratory at Petrolia, Tex.

H. B. NORTHRUP, who has been associate professor of metallurgy at the Pennsylvania State College, State College, Pa., for nine years, has resigned to become chief metallurgist of the Diamond Chain & Manufacturing Co., Indianapolis, Ind.

ALFRED M. STAEBLE, formerly editor of the *Blast Furnace and Steel Plant*, has assumed his new duties in the industrial section of the department of publicity of the Westinghouse Electric & Manufacturing Co., Pittsburgh, Pa.

IRVING JOHN STAFFORD has resigned his position as assistant superintendent of the No. 2 mill of the Strathmore Paper Co., at Woronoco, Mass., to accept a position as associate engineer in the department of technical control of the American Writing Paper Co., Holyoke, Mass. Prior to his entry into the paper industry, Mr. Stafford was associated with the Dow Chemical Co., Midland, Mich., as manufacturing chemist on electrolytic magnesium.

A. H. TAYLOR, who has been chief of the photometer section of the Bureau of Standards, has resigned to take up a research position with the Nela laboratories, where he will be associated with Dr. Luckiesh.

J. VAN ACKEREN, operating superintendent of the Koppers Co., arrived in New York July 28 on the S.S. Noordam from Rotterdam, after a visit of several months in Europe.

Obituary

JAMES MITCHELL, president and organizer of the Alabama Power Co., died at St. James, L. I., on July 22 after a year's illness from paralysis. Mr. Mitchell was born at Pembroke, Canada, fifty-four years ago, but his family moved to Milton, Mass., when he was a boy. As a young man he worked for the Thompson-Houston Co., now part of the Lynn works of the General Electric Co. He was a pioneer in electric railway development in South America, but during the past decade had devoted his time to his greatest work, the Alabama Power Co. Besides his widow, Mr. Mitchell is survived by two children, John Malcolm, a junior at Cornell, and Miss Marion Mitchell.

LUDWIG GATTERMANN, professor of chemistry at Freiburg, died on June 20, 1920. He was born in April, 1860, studied chemistry in Göttingen and was for a time assistant to Victor Meyer at Göttingen and later at Heidelberg. In 1900 he became professor of chemistry at the University of Freiburg. He contributed greatly to the development of organic chemistry. Among his most important works are: "Electrolytic Reduction of Aromatic Nitrogen Compound," "On Aromatic Thioketones," "Direct Synthesis of Aromatic Aldehyde," "Chemistry of Silicon," "Dyes and Other Derivatives of Anthraquinone" and a textbook on "Practical Methods of Organic Chemistry."

Current Market Reports

The Iron and Steel Market

Pittsburgh, July 30, 1920.

Rail transportation conditions, as regards the shipment of pig iron and steel products, have rounded the turn. The point is well passed at which the rate of pig iron and steel accumulating at works ceased to increase and the point has probably been reached, or at least closely approached, at which the total of accumulations is not increasing. The next period would be one of gradually moving the accumulations in addition to moving the current production. In the Chicago district there has already been somewhat of a clean-up, whereby the stocks of accumulated material are greatly reduced. In the Pittsburgh and Youngstown districts the shipments are still short of production, but not by as large a margin as formerly, and not a few mills have in the past week shipped approximately as much as they produced. The shipments do not invariably represent the current production, for some mills are shipping finished products from stock and at the same time accumulating semi-finished material, the object being to make the stocks of more mobile character, it being recognized that some of the finished steel made lately to customers' specifications would not be acceptable if not shipped until its turn came.

COAL CAR OUTLOOK BETTER

As noted in the last report, iron and steel interests were entertaining the hope that within a short time the coal mines will be supplied with as many cars as they were able to load, whereupon any further increase in transportation would permit of more transportation being given to the iron and steel industry. Evidences are accumulating that the point is near at hand. One coal operator in the Pittsburgh district, for illustration, has admitted that with his present 70 per cent car supply he is loading all the coal his miners will produce. They could produce more if they worked full time, but that they will not do as a rule, when the tonnage rate is where it stands.

There is no question that the railroads as a whole are functioning better from week to week, whereby the total

volume of transportation is increasing. It is a case of reducing inefficiency of the physical equipment, not of additions to equipment. There will be additions in future, but no large additions in the nearby future. The iron and steel industry is convinced that the railroads are not operated as efficiently as they could or should be. This judgment is supported by various comparisons, one of these being that certain roads which in the past were considered rather poorly equipped physically and mentally are now functioning much better than other roads that have had very good reputations.

TRANSPORTATION AND STEEL CONSUMPTION

The steel industry considers transportation the most vital factor, or at least one of the two most vital factors in the matter of steel trade prosperity. Better transportation conditions are wanted not merely for the sake of steel products being moved to customers with more facility, but largely for the sake of steel consumers and potential consumers receiving such transportation service upon their other raw materials or upon their finished products that they will have occasion to operate at better rates and thus have greater use for steel.

The other of the two most important factors bearing upon the nearby future of the steel trade is the matter of money and credit. With the present strained financial situation there is no room for sufficient initiative in the undertaking of large construction work, and this applies to the construction of railroad facilities as well as of other things. In the conduct of the present steel business there is no lack of money apparent, but expansion is prevented. The pig iron and steel producers are carrying little if any paper of their customers, payments being good, nor are the producers borrowers to any extent. The business that is being done is financed without any difficulty, but growth in demand is restricted by present financial conditions.

QUIET MARKETS

The pig iron, semi-finished steel and finished steel markets have all been very quiet in the past week, even quieter than in previous weeks of the proverbially dull midsummer period. There is no definite trend by which the future can be gaged. With such a light demand for steel one might expect steel prices to decline, and undoubtedly many buyers do entertain such an expectation. Pig iron, however, is high relative to steel prices, and yet pig iron, as quotable in the open market, is displaying a distinct advancing tendency. Bessemer, basic and foundry iron in the local market are all quotable \$1 a ton higher, at \$47 for bessemer and \$46 for basic and foundry, f.o.b. valley furnaces. The advances have occurred through there being insistent demand for relatively small lots of prompt iron, when it is the delivery rather than the iron that the purchaser is buying, for the purchaser may indeed have considerable tonnages of iron due him on old and lower priced contracts, the iron not being shipped because cars are not available or because the furnace has had its output restricted by coke scarcity.

In prices for finished steel products for prompt shipment there has been a gradual lowering for many weeks past, prompt prices tending to reach the level of prices for deliveries within a few months. While this trend continues, in general, sheets have had a movement of their own and are higher priced for prompt shipment than a fortnight ago.

The Chemical and Allied Industrial Markets

New York, July 30, 1920.

The chemical market is in the grip of the usual dull midsummer season. Very few inquiries are heard and as a result the market for the most part remains in the same position as previously reported. It is noticeable, however, that this condition is having a salutary effect upon the trade as a whole, as it gives producers a chance to catch up on some of their overdue contracts, and dealers will be better able to meet the fall buying season when it arrives. The acids have remained quiet during the week, the only change being in citric, which is held firm by producers at 80c. in car lots and 82@84c. in less than car lots. Most of actual trading in alum recently is resale, quotations running at 6@6½c. per lb., while the manufacturers' price

has continued at 4½c. With the increase in the cost of production, however, the leading concerns have advanced their quotations to 5@5½c. for ammonia lump and 8@8½c. for potash lump, while chrome lump holds firm at previous levels of 15½@18c. per lb. for car lots. As was noted some weeks ago, the barium chloride situation seemed to be becoming easier and with the arrival of fresh supplies in this market the quotation has come down from a nominal figure of \$170@\$180 per ton to an actual figure of \$160, at which price there were actual orders placed during the week. Copperas also came down and although there is not enough material on spot to meet the demand the current quotation is \$2.20@\$2.50 per cwt., against \$2.75@\$3, the recently prevailing price. Potassium salts remained firm in general with chlorate advanced to 19@19½c. per lb., due principally to the difficulty manufacturers are experiencing in increased plant expenses.

COAL-TAR PRODUCTS

This market seems to have assumed a healthier tone, although there has not been any noticeable upward price movement. The reason for this is larger supplies. The present dullness caused by the dropping out of the buying market of tanners and textile interests is rather an advantage to coal-tar producers, giving them the opportunity to catch up in their contracts. Naphthalene is the exception, as no material in even medium sized quantities is available. Resale lots are still changing hands at figures ranging between 19c. and 21c. per lb. The improvement in supplies of dinitrotoluol has caused a slight drop in this item, which can be had at 35@40c. per lb., against 40@45c. of the previous week. H acid can also be obtained in larger quantities, with \$2@\$2.25 per lb. the prevailing quotations, and orthonitrotoluol, which has been quiet for some time, is listed at 35@40c. per lb.

NAVAL STORES

Quotations on rosin are the same as last reported, although there was considerable activity the first part of the week and there was a general advance of about 30c., but during the last few days the tone of the market has weakened and today the former prices prevail. Turpentine fared a little better, making an advance of 11c. and keeping in that position, current quotation now being about \$1.69 per gal., and this is practically a nominal figure, as there is scarcely any material available in the local market.

OILS

The prevailing dullness in this market remains unbroken. Buying interest in cottonseed is quiet and evidently awaiting a price readjustment on the new seed. Current quotation is \$13.40@\$14. There has been a firmer tone manifested in soya bean during the week, although business is by no means near normal at the prevailing figure of 10½c. per lb. Peanut oil is one of the weakest items on the list, inquiries being few. Offerings continue in small way on a 12½@12½c. per lb. basis.

The Baltimore Market

Baltimore, Md., July 29, 1920.

The fertilizer manufacturers are now beginning to show more interest in the purchase of their supplies for the fall as well as next spring season. Labor conditions are still very unsatisfactory, with no indications of any improvement, and it is the consensus of opinion of the manufacturers that they will experience considerable difficulty during the next few months in getting enough cars to ship their products.

During the past week the market on cottonseed meal has eased up, and this material is now obtainable for summer as well as fall shipments at less than tankage, even without taking into consideration the value of phosphoric acid and potash in cottonseed meal. Off-grade meal for August shipment is quoted as low as \$8 per unit of ammonia delivered Baltimore, no charge for phosphoric acid, potash or bags. Prime 43 per cent meal is being quoted for September-December shipment from the South at \$8.25@\$8.50 per unit of ammonia. Figuring the value of phosphoric acid, potash and bags, this brings the ammonia down to the basis of about \$7.60@\$7.85 per unit.

The acid phosphate market during the next few months is closely sold up, and on account of the car situation, producers are not disposed to commit themselves to too heavy a tonnage to move by cars, even during the later months. Prices remain unchanged at \$20 per ton for 16 per cent grade, in bulk, with run of pile testing 17 to 18 per cent being quoted at \$19.50 per ton of 2,000 lb., in bulk, basis 16 per cent. It is not so much a question of price with the producers as it is of being able to fill the orders and take care of their regular trade. There is no improvement in the phosphate rock situation, and occasional resale lots are readily taken up with prices ranging from \$15 to \$16 per gross ton ex vessels Baltimore. Sulphuric acid is also in short supply, and when all conditions are taken into consideration, it can be readily understood that the present market will be maintained for some months to come.

TANKAGE

There is practically none of this material now finding its way from the West to this section, as the fertilizer manufacturers realize it is impossible for them to compete for the desired makes with buyers who require this material for feeding purposes. The Eastern market remains unchanged, and prevailing price of \$8 per unit of ammonia and 10c. per unit of B.P.L., basic c.a.f. Baltimore, is still considered a shade under the market, but business can be worked at this figure. Some of the producers have their views pitched at this price f.o.b. shipping point, but buyers are slow to take hold at this figure.

NITRATE OF SODA

This article has been somewhat more active than for some time past, and with the falling sterling exchange, it is possible to shade \$4 per 100 lb. for October-December arrivals, and \$4.10 for January-April arrivals. However, any material improvements in the exchange situation will naturally be reflected in importers' prices.

POTASH

During the past week there has been considerable agitation over the fact that the German syndicate is trying to hold up the American buyers by charging them twice as much for potash as they sell to other countries. While there is no concerted action on the part of American fertilizer manufacturers, at the same time they have been strongly advised to defer the purchase of their requirements of potash over the remainder of this year another thirty days at least, which is felt will have the desired effect on the German Government, which from reports has already been bringing pressure to bear on the syndicate to reduce prices to an equitable basis in order to move a good tonnage. Up to the present time only about one-fifth of the tonnage of German potash has been shipped since April 5 that would have been shipped had prices been on a reasonable basis. Spot stocks, however, are being firmly held on the basis of \$2.20@2.25 per unit for kainit and \$2.65 for muriate, with no manure salt offering and no important shipments on the way. The demand, however, is very light, as fall mixtures are usually much lower in potash than during the spring season.

FISH SCRAP

The catch of fish in the Chesapeake Bay remains moderate and stiffening up in prices is noticeable, while the nominal market is \$7.60 and 10c. for dry scrap f.o.b. factories. This price is subject to catch and "if made." Producers are well sold up and every indication points to the fish factories having a banner season.

BONE MEAL

There is no change in the market, which is practically bare of both raw and steamed bone meal, 3 and 50 per cent still being held at \$54 per ton, in buyers' bags, f.o.b. Baltimore, and every indication points to this price being maintained. Raw bone meal is a trifle firmer and very scarce; resale lots now being held at \$64 per ton in second-hand bags f.o.b. basis Baltimore.

Molybdic, C. P.....	lb.	4.00 - 4.50	4.50 - 5.00
Muriatic, 20 deg. (see hydrochloric).....	lb.		
Nitric, 40 deg.....	lb.	.06 - .07	.07 1/2 - .08 1/2
Nitric, 42 deg.....	lb.	.07 1/2 - .08	.08 1/2 - .09 1/2
Oxalic, crystals.....	lb.	.55 - .57	.60 - .65
Phosphoric, Ortho, 50 per cent solution.....	lb.	.14 - .23	.24 - .25
Picric.....	lb.	.28 - .35	.40 - .50
Pyrogallol, resublimed.....	lb.	2.25 - 2.55	2.60 - 2.65
Sulphuric, 60 deg, tank cars.....	ton	14.00 - 16.00	
Sulphuric, 60 deg, drums.....	ton		
Sulphuric, 66 deg, tank cars.....	ton	16.00 - 17.00	18.00 - 20.00
Sulphuric, 66 deg, drums.....	ton	26.00 - 28.00	
Sulphuric, 66 deg, carboys.....	ton		
Sulphuric, fuming, 20 per cent (oleum) tank cars.....	ton	27.00 - 30.00	37.00 - 42.00
Sulphuric, fuming, 20 per cent (oleum) drums.....	ton	28.00 - 30.00	38.00 - 42.00
Sulphuric, fuming, 20 per cent (oleum) carboys.....	ton	32.00 - 35.00	40.00 -
Tannic, U. S. P.....	lb.	1.45 - 1.50	1.55 - 1.65
Tannic (tech).....	lb.	.60 - .70	.80 - .90
Tartaric, crystals.....	lb.		.74 - .77
Tungstic, per lb. of WtO.....	lb.		1.20 - 1.40
Alcohol, Ethyl (nominal).....	gal.	5.10 - 5.50	6.00 - 7.00
Alcohol, Methyl, 95%.....	gal.		3.25 - 3.30
Alcohol, Methyl, pure.....	gal.		3.50 - 3.55
Alcohol, denatured, 188 proof (nominal).....	gal.		1.10 - 1.15
Alcohol, denatured, 190 proof (nominal).....	gal.		1.05 - 1.10
Alum, ammonia lump.....	lb.	.05 - .05 1/2	.05 1/2 - .06
Alum, potash lump.....	lb.	.08 - .08 1/2	.09 - .09 1/2
Alum, chrome lump.....	lb.	.15 1/2 - .18	.19 - .20
Aluminium sulphate, commercial.....	lb.	.04 1/2 -	
Aluminium sulphate, iron free.....	lb.	.06 -	
Aqua ammonia, 26 deg, drums (750 lb.).....	lb.	.09 1/2 - .10 1/2	.11 - .12
Ammonia, anhydrous, cylinders (100-150 lb.).....	lb.	.34 - .35	.35 - .40
Ammonium carbonate, powder.....	lb.	.16 - .16 1/2	.17 - .18
Ammonium chloride, granular (white sal-ammoniac) (nominal).....	lb.	.16 - .16 1/2	.17 - .18
Ammonium chloride, granular (gray sal-ammoniac).....	lb.	.13 - .13 1/2	.13 1/2 - .14 1/2
Ammonium nitrate.....	lb.	.09 - .10	.11 - .14
Ammonium sulphate.....	lb.	.07 - .07 1/2	.08 1/2 -
Amlyacetate.....	gal.		5.00 -
Amlyacetate tech.....	gal.		4.75 - 5.25
Arsenic, oxide, lumps (white arsenic).....	lb.	.15 1/2 - .16	.16 1/2 - .17
Arsenic, sulphide, powdered (red arsenic).....	lb.	.20 - .21	.22 - .25
Barium chloride.....	ton	150.00 - 160.00	
Barium dioxide (peroxide).....	lb.	.21 - .23	.24 - .25
Barium nitrate.....	lb.	.09 - .11	.11 - .12
Barium sulphate (precip) (blanc fixe).....	lb.	.04 1/2 - .05	.05 1/2 - .06
Bleaching powder (see calcium hypochlorite).....			
Blue vitriol (see copper sulphate).....			
Borax (see sodium borate).....			
Brimstone (see sulphur, roll).....			
Bromine.....	lb.	.70 - .90	1.00 - 1.05
Calcium acetate.....	cwt.	3.50 - 3.55	
Calcium carbide.....	lb.	.04 1/2 - .04 1/2	.04 1/2 - .05 1/2
Calcium chloride, fused, lump.....	ton	25.00 - 30.00	35.00 - 45.00
Calcium chloride, granulated.....	lb.	.01 1/2 - .01 1/2	.02 - .03 1/2
Calcium hypochlorite (bleaching powder).....	cwt.		4.50 - 6.50
Calcium peroxide.....	lb.		1.50 - 1.70
Calcium phosphate, monobasic.....	lb.		.75 - .80
Calcium sulphate, pure.....	lb.		.25 - .30
Carbon bisulphide.....	lb.	.08 - .09	.10 - .11
Carbon tetrachloride, drums.....	lb.	.14 - .15	.16 - .17
Carbonyl chloride (phosgene).....	lb.		.80 - 1.05
Caustic potash (see potassium hydroxide).....			
Caustic soda (see sodium hydroxide).....			
Chlorine, gas, liquid-cylinders (100 lb.).....	lb.	.09 - .09 1/2	.10 - .10 1/2
Chloroform.....	lb.	.30 - .35	.36 - .38
Cobalt oxide.....	lb.		2.00 - 2.05
Copperas (see iron sulphate).....			
Copper carbonate, green precipitate.....	lb.	.27 - .28	.29 - .31
Copper cyanide.....	lb.		.65 - .70
Copper sulphate, crystals.....	lb.	.08 - .09	.09 - .09 1/2
Cream of tartar (see potassium bitartrate).....			
Epsom salt (see magnesium sulphate).....			
Ethyl Acetate Com. 85%.....	gal.	1.35 -	1.40 -
Ethyl Acetate pure (acetic ether 98% to 100%).....			1.75 -
Formaldehyde, 40 per cent (nominal).....	gal.		.57 - .65
Fusel oil, ref.....	gal.		5.25 - 6.00
Fusel oil, crude (nominal).....	gal.		
Glauber's salt (see sodium sulphate).....			
Glycerine.....	lb.		.26 1/2 - .28 1/2
Iodine, resublimed.....	lb.	6.30 - 4.35	4.40 - 4.45
Iron oxide, red.....	lb.		.03 - .20
Iron sulphate (copperas).....	cwt.		2.20 - 2.50
Lead acetate, normal.....	lb.		.13 - .16
Lead arsenate (paste).....	lb.	.11 - .12	.13 - .17
Lead nitrate, crystals.....	lb.		.90 - 1.00
Litharge.....	lb.	.14 - .15	.15 1/2 - .16
Lithium carbonate.....	lb.		1.50 -
Magnesium carbonate, technical.....	lb.	.12 - .14	.15 - .15 1/2
Magnesium sulphate, U. S. P.....	100 lb.	3.00 - 3.55	4.00 - 4.50
Magnesium sulphate, commercial.....	100 lb.		3.25 - 3.60
Nickel salt, double.....	lb.		.14 - .15
Nickel salt, single.....	lb.		.13 - .14
Phosgene (see carbonyl chloride).....			
Phosphorus, red.....	lb.	.50 - .55	.60 - .65
Phosphorus, yellow.....	lb.		.35 - .37
Potassium bichromate.....	lb.	.50 - .55	.57 - .60

	Carlots	Less Carlots
Potassium bitartrate (cream of Tartar).....	lb. \$0.52 - \$0.56	\$0.57 - \$0.58
Potassium bromide, granular.....	lb. .90 - .95	.90 - .95
Potassium carbonate, U. S. P.....	lb. .47 - .50	.47 - .50
Potassium carbonate, crude.....	lb. .20 - .25	.26 - .28
Potassium chlorate, crystals.....	lb. .17 - .17 1/2	.18 - .20
Potassium hydroxide (caustic potash).....	lb. .30 - .33	.35 - .38
Potassium iodide.....	lb. .17 - .17 1/2	.19 - .21
Potassium nitrate.....	lb. .75 - .80	.85 - .95
Potassium permanganate.....	lb. .90 - 1.00	1.05 - 1.10
Potassium prussiate, red.....	lb. .32 - .36	.35 - .40
Potassium prussiate, yellow.....	ton \$225.00 - 240.00	
Potassium sulphate (powdered).....	ton \$225.00 - 240.00	
Rochelle salts (see sodium potas. tartrate)		
Salammoniac (see ammonium chloride)		
Salt soda (see sodium carbonate)		
Salt cake.....	ton 40.00 - 50.00	
Silver cyanide (nominal).....	os. 1.25 - .70	
Silver nitrate (nominal).....	os. 3.20 - 3.50	
Soda ash, light.....	100 lb. 3.55 - 3.65	
Soda ash, dense.....	100 lb. 10 - 15	
Sodium acetate.....	100 lb. 2.50 - 2.75	
Sodium bicarbonate.....	100 lb. 22 - 24	
Sodium bichromate.....	100 lb. 7.00 - 8.00	
Sodium bisulphate (nitre cake).....	100 lb. .08 - .10	
Sodium bisulphate Powdered, U.S.P.....	100 lb. .09 - .10	
Sodium borate (borax).....	100 lb. 1.50 - 1.80	
Sodium carbonate (sal soda).....	100 lb. 11 - 12	
Sodium chlorate.....	100 lb. 32 - 35	
Sodium cyanide, 96-98 per cent.....	100 lb. 18 - 20	
Sodium fluoride.....	100 lb. 6.25 - 7.00	
Sodium hydroxide (caustic soda).....	100 lb. .03 - .04	
Sodium hyposulphate.....	100 lb. 2.50 - 3.25	
Sodium molybdate.....	100 lb. 3.00 - 3.25	
Sodium nitrate.....	100 lb. 16 - 18	
Sodium nitrite.....	100 lb. 32 - 35	
Sodium peroxide, powdered.....	100 lb. .031 - .04	
Sodium phosphate, dibasic.....	100 lb. .39 - .40	
Sodium potassium tartrate (Rochelle salts).....	100 lb. 23 - 27	
Sodium prussiate, yellow.....	100 lb. .014 - .015	
Sodium silicate, solution (40 deg.).....	100 lb. .024 - .03	
Sodium silicate, solution (60 deg.).....	100 lb. 1.60 - 1.70	
Sodium sulphate, crystals (Glauber's salt) cwt.....	100 lb. .09 - .10	
Sodium sulphide, crystals, 60-62 per cent (rope) lb.....	100 lb. .04 - 0.41	
Sodium sulphite, crystals.....	100 lb. .17 - .18	
Strontium nitrate, powdered.....	100 lb. .08 - .09	
Sulphur chloride red.....	100 lb. 25.00 - 30.00	
Sulphur, crude.....	100 lb. .09 - .10	
Sulphur dioxide, liquid, cylinders.....	100 lb. 3.80 - 4.35	
Sulphur (sublimed), flour.....	100 lb. 3.40 - 3.90	
Sulphur, roll (brimstone).....	100 lb. 42 - 44	
Tin bichloride (stannous).....	100 lb. 16 - 18	
Tin oxide.....	100 lb. 13 - 14	
Zinc carbonate, precipitate.....	100 lb. 45 - 49	
Zinc chloride, gran.....	100 lb. 11 - 12	
Zinc cyanide.....	100 lb. 17 - 25	
Zinc dust.....	100 lb. .031 - .031	
Zinc oxide, U. S. P.....	100 lb. .031 - .031	
Zinc sulphate.....	100 lb. .04 - .06	

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude.....	lb. \$1.40 - \$1.50
Alpha naphthol, refined.....	lb. 1.0 - 1.20
Alpha naphthylamine.....	lb. .53 - .56
Aniline oil, drums extra.....	lb. .40 - .42
Aniline salts.....	lb. .90 - 1.00
Anthracene, 80% in drums (100 lb.).....	lb. 2.00 - 2.10
Benzaldehyde (f.f.c.).....	lb. 1.35 - 1.40
Benzidine, base.....	lb. 1.15 - 1.25
Benzidine, sulphate.....	lb. .90 - 1.00
Benzoic acid, U. S. P.....	lb. .80 - .90
Benzonitrile, U. S. P.....	lb. .39 - .40
Benzol, pure, water-white, in drums (100 lb.).....	gal. .33 - .38
Benzol, 90%, in drums (100 lb.).....	gal. .25 - .35
Benzyl chloride, 95-97%, refined.....	lb. .25 - .35
Benzyl chloride, tech.....	lb. 3.50 - 4.00
Beta naphthol benzoate (nominal).....	lb. .85 - .95
Beta naphthol, sublimed (nominal).....	lb. 2.25 - 2.40
Beta naphthylamine, sublimed.....	lb. .18 - .19
Cresol, U. S. P., in drums (100 lb.).....	lb. .23 - .25
Ortho-cresol, in drums (100 lb.).....	lb. 1.05 - 1.15
Cresylic acid, 97-99%, straw color, in drums.....	gal. 1.00 - 1.05
Cresylic acid, 95-97%, dark, in drums.....	gal. .65 - .75
Cresylic acid, 50%, first quality, drums.....	gal. .08 - .10
Dichlorobenzol.....	lb. 1.50 - 1.60
Diethylaniline.....	lb. 1.35 - 1.45
Dinitrobenzol.....	lb. .30 - .37
Dinitrochlorobenzol.....	lb. .45 - .55
Dinitronaphthalene.....	lb. .40 - .45
Dinitrophenol.....	lb. .35 - .40
Dinitrotoluol.....	lb. .38 - .40
Dip oil, 25%, tar acids, car lots, in drums.....	gal. .80 - .85
Diphenylamine (nominal).....	lb. 2.00 - 2.25
H-acid (nominal).....	lb. 1.25 - 1.30
Metaphenyl-nediamine.....	lb. .18 - .20
Monochlorobenzol.....	lb. 2.00 - 2.40
Monothylaniline.....	lb. .19 - .20
Naphthalene crushed, in bbls. (250 lb.).....	lb. .75 - .85
Naphthalene, flake.....	lb. .14 - .19
Naphthalene, balls.....	lb. .40 - .50
Naphthionic acid, crude.....	lb. .18 - .25
Nitrobenzol.....	lb. 3.25 - 4.25
Nitro-naphthalene.....	lb. .15 - .20
Nitro-toluol.....	lb. .80 - 1.25
Ortho-amidophenol.....	lb. .25 - .40
Ortho-dichlor-benzol.....	lb. .35 - .40
Ortho-nitro-phenol.....	lb. 2.50 - 3.00
Ortho-nitro-toluol.....	lb. 2.50 - 3.00
Ortho-toluidine.....	lb. .08 - .12
Para-amidophenol, base.....	lb. 1.35 - 1.40
Para-amidophenol, HCl.....	
Para-dichlor-benzol.....	
Paranitraniline.....	

Para-nitro-toluol.....	lb. 1.35 - 1.50
Paraphenylenediamine.....	lb. 2.50 - 2.65
Paratoluidine.....	lb. 2.00 - 2.25
Phthalic anhydride.....	lb. .60 - .70
Phenol, U. S. P., drums (dest.), (240 lb.).....	lb. 12 - 20
Pyridin.....	gal. 2.00 - 3.50
Resorcin, technical.....	lb. 4.25 - 4.50
Resorcin, pure.....	lb. 6.25 - 6.75
Salicylic acid, tech., in bbls. (110 lb.).....	lb. .50 - .52
Salicylic acid, U. S. P.....	lb. .50 - .60
Salol.....	lb. .90 - 1.00
Solvent naphtha, water-white, in drums, 100 gal.....	gal. .33 - .35
Solvent naphtha, crude, heavy, in drums, 100 gal.....	gal. .23 - .26
Sulphanilic acid, crude.....	lb. .32 - .35
Toluidine.....	lb. 1.70 - 2.50
Toluidine, mixed.....	lb. .45 - .55
Toluol, in tank cars.....	gal. .35 - .40
Toluol, in drums.....	gal. .38 - .40
Xylidine, drums, 100 gal.....	gal. .50 - .65
Xylol, pure, in drums.....	gal. .37 - .45
Xylol, pure in tank cars.....	gal. .35 - .45
Xylol, commercial, in drums, 100 gal.....	gal. .37 - .45
Xylol, commercial, in tank cars.....	gal. .23 - .27

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark.....	lb. \$0.36 - \$0.39
Beeswax, refined, light.....	lb. .39 - .40
Beeswax, white pure.....	lb. .63 - .68
Carnauba, No. 1, (nominal).....	lb. 1.00 - 1.05
Carnauba, No. 2, regular (nominal).....	lb. .85 - .88
Carnauba, No. 3, North Country.....	lb. .35 - .36
Japan.....	lb. .19 - .19 1/2
Montan, crude.....	lb. .23 - .25
Paraffine waxes, crude match wax (white) 105-110 m.p.....	lb. .09 - .09 1/2
Paraffine waxes, crude, scale 124-126 m.p.....	lb. .10 - .10 1/2
Paraffine waxes, refined, 118-120 m.p.....	lb. .113 - .12
Paraffine waxes, refined, 125 m.p.....	lb. .124 - .125
Paraffine waxes, refined, 128-130 m.p.....	lb. .143 - .151
Paraffine waxes, refined, 133-135 m.p.....	lb. .161 - .17
Paraffine waxes, refined, 135-137 m.p.....	lb. .171 - .181
Stearic acid, single pressed.....	lb. .24 - .25
Stearic acid, double pressed.....	lb. .25 - .26
Stearic acid, triple pressed.....	lb. .27 - .28

NOTE—Paraffine waxes very scarce.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940.....	gal. \$2.30
Pine oil, pure, dest. dist.....	gal. 1.80
Pine tar oil, ref., sp. gr. 1.025-1.035.....	gal. .48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank car f.o.b. Jacksonville, Fla.....	gal. .35
Pine tar oil, double ref., sp. gr. 0.965-0.990.....	gal. .85
Pine tar, ref., thin, sp. gr. 1.080-1.060.....	gal. .36
Turpentine, crude, sp. gr. 0.900-0.970.....	gal. 2.00
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990.....	gal. .35
Pine wood creosote, ref.....	gal. .52

Naval Stores

The following prices are f.o.b. New York, for carload lots.

Rosin B-D, bbl.....	280 lb. \$12.25 - \$16.25
Rosin E-J.....	280 lb. 16.60 - 16.75
Rosin K-N.....	280 lb. 17.00 - 17.20
Rosin W, G-W W.....	280 lb. 17.25 - 17.50
Wood rosin, bbl.....	280 lb. 15.00
Spirits of turpentine.....	gal. 1.69
Wood turpentine, steam dist.....	gal. .
Wood turpentine, dest. dist.....	gal. .
Pine tar pitch, bbl.....	200 lb. 8.50
Tar, kiln burned, bbl (500 lb.).....	gal. 14.50 - 15.00
Retort tar, bbl.....	500 lb. 15.00 - 15.50
Rosin oil, first run.....	gal. .70
Rosin oil, second run.....	gal. .73
Rosin oil, third run.....	gal. .92

Solvents

73-76 deg. steel bbls. (85 lb.).....	gal. \$0.40
70-72 deg. steel bbls. (85 lb.).....	gal. .38
68-70 deg. steel bbls. (85 lb.).....	gal. .37
V. M. and P. naphtha, steel bbls. (85 lb.).....	gal. .29

Crude Rubber

Para Upriver fine.....	lb. \$0.32 - \$0.33
Upriver coarse.....	lb. .23 - .24
Upriver caucho ball.....	lb. .23 - .24
Plantation—First latex crepe.....	lb. .32 - .33
Ribbed smoked sheets.....	lb. .31 - .32
Brown crepe, thin, clean.....	lb. .30 - .31
Amber crepe No. 1.....	lb. .30 - .31

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls.....	lb. \$0.17 - \$0.19
Castor oil, AA, in bbls.....	lb. .19
China wood oil, in bbls.....	lb. .18 - .19
Cocoonut oil, Ceylon grade, in bbls.....	lb. .16 - .17
Cocoonut oil, Cochun grade, in bbls (nominal).....	lb. .171 - .17
Corn oil, crude, in bbls.....	lb. .16 - .16 1/2
Cottonseed oil, crude (f.o.b. mill).....	lb. .10 - .11
Cottonseed oil, summer yellow.....	lb. .131 - .13
Cottonseed oil, winter yellow.....	lb. .19
Linseed oil, raw, car lots (domestic).....	gal. 1.20
Linseed oil, raw, tank cars (domestic).....	gal. 1.30
Linseed oil, boiled, car lots (domestic).....	gal. 1.35

Olive oil, commercial.....	gal.	3.00	—	3.10
Palm, Lagos.....	lb.	.101	—	.10
Palm, bright red.....	lb.	.101	—	.10
Palm, Niger.....	lb.	.11	—	.12
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.121	—	.121
Peanut oil, refined, in bbls.....	lb.	.17	—	.18
Rapeseed oil, refined in bbls.....	gal.	1.65	—	
Rapeseed oil, blown, in bbls.....	gal.	1.70	—	
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.14	—	.14
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.101	—	.11

FISH

Winter pressed Menhaden.....	gal.	\$0.90	—	\$1.05
Yellow bleached Menhaden.....	gal.	0.95	—	1.05
White bleached Menhaden.....	gal.	1.00	—	1.25
Blown Menhaden.....	gal.	1.00	—	1.20

Miscellaneous Materials

All f. o. b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.	net ton	\$22.00	—	\$25.00
Barytes, ground, off color, f.o.b. Kings Creek	net ton	18.00	—	20.00
Barytes, crude, 88% to 94% ba., Kings Creek	net ton	8.00	—	10.00
Barytes, ground, white, f.o.b. Cartersville, Ga.	net ton	23.00	—	25.00
Barytes, ground, off-color, f.o.b. Cartersville	net ton	16.00	—	19.00
Barytes, crude, 88% to 94% ba., Cartersville	net ton	12.00	—	
Barytes, floated, f.o.b. St. Louis	net ton	26.50	—	28.00
Barytes, crude, min. 98% ba., Missouri	net ton	11.00	—	11.25
Blanc fixe, dry.....	lb.	.05	—	.06
Blanc fixe, pulp.....	net ton	60.00	—	80.00
Casein.....	lb.	.15	—	.18
Chalk, domestic, extra light.....	lb.	.05	—	.06
Chalk, domestic, light.....	lb.	.04	—	.05
Chalk, domestic, heavy.....	lb.	.04	—	.05
Chalk, English, extra light.....	lb.	.05	—	.07
Chalk, English, light.....	lb.	.05	—	.06
Chalk, English, dense.....	lb.	.04	—	.05
China clay, (Kaolin) crude, f.o.b. mines, Georgia	net ton	9.00	—	12.00
China clay (Kaolin) washed, f.o.b. Georgia	net ton	12.00	—	15.00

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—The Amer. Bolt Wks., 39th St. and 10th Ave. N., has awarded the contract for the construction of a steel addition to forge shops, to C. M. Allen. Estimated cost, \$25,000.

Arizona

MESA—The South Side Community Hospital, c/o Berlin, Swern & Randall, archts., 19 South La Salle St., Chicago, is having preliminary plans prepared for the construction of a 3-story, 42x100-ft. hospital. A small chemical laboratory will be installed in same. Estimated cost, \$125,000.

Connecticut

BRIDGEPORT—The Amer. Tube & Stamping Co., 471 Hancock Ave., will build a 1-story, 50x160-ft. annealing building on Wordin Ave. Estimated cost, \$30,000. Work will be done by day labor.

SUFFIELD—The Fords Wawbeek Springs, Inc., c/o Walter E. Dibble, archt., 317 Main St., Springfield, Mass., will soon award the contract for a 1- and 2-story spring water plant. Estimated cost, \$50,000.

WATERBURY—M. J. Daly & Sons, 543 Bank St., has awarded the contract for the construction of a 1- and 3-story factory for the manufacture of sheet metal, to the G. S. Chaffield Co., 138 Division St. Estimated cost, \$85,000.

WATERVILLE—The Herbecker & Rowland Mfg. Co., Main St., has awarded the contract for the construction of a 3-story, 40x180-ft. factory for the manufacture of metal goods, to the Torrington Bldg. Co., 197 Water St. Estimated cost, \$100,000.

WINDSOR LOCKS—C. H. Dexter & Sons, Inc., has awarded the contract for altering the present tissue paper manufacturing building, to the Bent-Bartlett Co., 43 Ann St., Hartford. Estimated cost, \$28,000.

Georgia

SAVANNAH—The Bd. Educ. plans to build a 3-story, 148-224-ft. school. A chemical laboratory will be installed in same. Estimated cost, about \$1,000,000. William B. Ittner, Bd. Educ., St. Louis, Mo., archt.

Illinois

CHICAGO—The Enterprise Paint Mfg. Co., 854 West Van Buren St., has awarded the contract for the construction of a 5-story, 44x60-ft. paint factory on Van Buren and Peoria Sts., to the O. W. Rosenthal Co., 84 East Jackson St. Estimated cost, \$50,000.

GRANITE CITY—The Bd. Educ. is having plans prepared for the construction of a 3-story high school. A chemical laboratory will be installed in same. Estimated cost, \$280,000. William B. Ittner, Bd. Educ. Bldg., St. Louis, Mo., archt.

Indiana

GARY—The Universal Slag Brick & Tile Co. is building a 1-story, 100x200-ft. brick plant. Estimated cost, \$200,000. Silica, Brick & Eng. Co., engr.

Iowa

DES MOINES—The Mid-West Steel Co., c/o Des Moines Steel Co., 4th St. south of Tuttle St., plans to build a 2-story steel manufacturing plant. Estimated cost, \$200,000. J. VanLew, pres.

NEWTON—The Newton Fdry Co. has awarded the contract for the construction of a 2-story, 106x300-ft. foundry, to the A. H. Newman Co., 517 Hubbell Bldg., Des Moines. Estimated cost, \$100,000.

Louisiana

NEW ORLEANS—S. Ohnstein will soon award the contract for the construction of a 1-story factory on Colapessa St., for the Union Paper Products Co., 109 Tchoupitoulas St. Estimated cost, \$125,000. Emile Weil, Whitney Central Bank Bldg., archt.

Maryland

BALTIMORE—The Natl. Bitulthic Enamel & Paint Co., Lawrence and Woodall Sts., will receive bids about Aug. 9 for the construction of a 3-story, 100x150 ft. addition to the enamel and paint plant. Estimated cost, \$100,000. J. R. Broderich, mgr.

Massachusetts

EAST EVERETT—The Boston Varnish Co., 2d St., has awarded the contract for the construction of a 1-story, 40x60-ft. addition and altering the present plant on East Summer St., to J. E. Locatelli Co., Inc., 46 Cornhill St., Boston. Estimated cost, \$30,000. Noted July 21.

HOLYOKE—The Hampden Glazed Paper & Card Co., River Side, has awarded the contract for the construction of a 4-story, 92x291 ft. factory on Water St., to the Casper Ranger Constr. Co., 201 Devonshire St., Boston, at \$165,000.

WHEELWRIGHT—The George W. Wheelwright Paper Co., 70 Franklin St., Boston, has awarded the contract for the construction of a concrete sedimentation tank at its Hardwick mill, here, to the H. P. Cummings Constr. Co., Ware.

Michigan

DETROIT—The General Forgings Corp., c/o J. D. Edwards, 54 Lafayette Blvd., plans to build a 2-story, 65x210-ft. drop forging shop.

Minnesota

MINNEAPOLIS—The Western Chemical Co. plans to build a 3- to 5-story patent medicine factory on Malcolm Ave. and University Ave., South. Chemical equipment will be installed in same. Estimated cost, from \$125,000 to \$150,000. A. G. Kranz, Hutchinson, pres. Downs & Eads, 803 Phoenix Bldg., archts.

Missouri

BROOKFIELD—The School Bd. is having preliminary plans prepared for the construction of a 2-story school. General chemical laboratories will be installed in same. Estimated cost, \$105,000. A. W. Baker, secy. W. E. Hulac & Co., 309 Securities Bldg., Des Moines, archt. Noted June 30.

ST. LOUIS—The Hanke-Baer Chemical Co., 1710 Morgan St., plans to build a modern factory for the manufacture of jellies and preserves on King's Highway. Estimated cost, \$150,000.

New Jersey

EDGEWATER—The United States Aluminum Co. plans to construct a large addition to its plant.

JERSEY CITY—J. T. Iverson & Sons, manufacturers of steel, 230 West Side Ave., plan to build an addition to their plant. Estimated cost, \$50,000.

MONMOUTH JUNCTION—The Alcoholic Products Corp. has awarded the contract for the construction of a plant addition, to Barney Ahlers, 110 West 40th St., New York City. Estimated cost, \$50,000.

TRENTON—The Acme Rubber Co., East State St., has awarded the contract for the construction of a 1-story, 90x300-ft. rubber plant addition on East State St., to the N. A. K. Bugbee Co., 206 East Hanover St. Estimated cost, \$60,000.

Ohio

CANTON—The Timken Roller Bearing Co., Dueber Ave., plans to build a 1 and 1-story addition to present plant on 18th St., S. W. Estimated cost, \$75,000.

CLEVELAND—The Jordan Motor Car Co., 1052 East 152d St., has awarded the contract for the construction of a 2-story japanning building at 1070 East 152d St., to the Hunkin-Conkey Constr. Co., Century Bldg. Estimated cost, \$100,000.

CLEVELAND—The L. S. Leather Co., c/o E. B. Cassatt, East 13th St. and Euclid Ave., plans to build a 1-story, 100x300-ft. factory on Brogliev Rd. Estimated cost, \$100,000.

FOSTORIA—The Willys Light Corp., 221 Cherry St., Toledo, has awarded the contract for the construction of a 1-story, 120x211-ft. foundry for the manufacture of iron castings, to H. J. Spicker, Elm and Utica Sts., Toledo. Estimated cost, \$125,000.

MARION—George R. Gascoigne, consult. engr., 1446 East 116th St., Cleveland, has been engaged to report upon sewerage and sewage disposal improvements. Estimated cost, \$600,000. T. S. Cathera, city engr.

WARREN—The Bd. Educ., c/o J. Buckwaller, has awarded the contract for the construction of a 2-story, 125x150-ft. addition to the East Technical High School, and a 2-story, 110x182-ft. addition to the West Technical High School, to the Shustrump Co., Youngstown. Laboratory equipment will be installed in same. Estimated cost, \$850,000. Noted July 28.

Pennsylvania

ELYSBURG—The Bd. Educ. is having plans prepared for the construction of a 2-story, 60x80-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$100,000. Richter Lee, 32 South 17th St., Philadelphia, archt.

JOHNSTOWN—The Peris Products Co. has purchased a site on Sheridan Ave., and plans to build a 2-story, 47x157 ft. factory for the manufacture of soap products. Estimated cost, \$150,000.

PHILADELPHIA—The Electric Storage Battery, Allegheny and 19th Sts., has awarded the contract for the construction of a number of buildings, including a forming room, pig lead manufacturing building, jars and castings buildings, etc., to William Steele & Sons Co., 16th and Arch Sts.

PITTSBURGH—The Oliver Iron & Steel Co., 10th and Muriel Sts., has awarded the contract for the construction of a 2-story, 28x60-ft. water purification plant which will have a capacity of 20,000 gal. per hour, to the Cuthbert Bros. Co., Ressemer Bldg. Estimated cost, \$35,000.

Rhode Island

PROVIDENCE—J. F. Concannon, Chalkstone Ave., has awarded the contract for the construction of a 1-story, 75x125-ft. laundry, to the Interstate Constr. Co., 29 Weybosset St. Estimated cost, \$28,000.

PROVIDENCE—The Franklin Process Co., 29 Promenade St., has awarded the contract for the construction of a 2-story, 110x170-ft. dye house, to J. R. Bickford, 509 Westminster St. Estimated cost, \$150,000. Noted July 28.

Tennessee

MEMPHIS—The Continental Piston Ring Co., 650 Marshall St., is building a 160x217-ft. factory.

Texas

HOUSTON—The Trans-Continental Oil Co. plans to build a wax plant here. Estimated cost, \$750,000. W. S. Barwick, supt.

West Virginia

WHEELING—The city plans to install a mechanical filtration system. Estimated cost, \$1,500,000.

Wisconsin

CEDARBURG—Fred Schuette, City Clk., will receive bids until Aug. 24 for the installation of 2 sewage disposal tanks, etc.

MILWAUKEE—The Eslein Sheet Metal Wks., 1001 30th St., will build a 1-story, 30x120-ft. sheet metal works addition on 30th St. Estimated cost, \$8,000. Work will be done by day labor.

MILWAUKEE—The Patton Paint Co., 213 Lake St., has awarded the contract for the construction of a 2-story, 70x106-ft. varnish factory and a 60x112-ft. warehouse on Lake St., to the Amer. Contr. Co., 198 Milwaukee St. Estimated cost, \$180,000. Noted July 7.

SHEBOYGAN—The Tomah Rubber Wks., 176 16th St., Milwaukee, plans to build a 2-story, 80x160-ft. factory for the manufacture of rubber goods.

WAUKESHA—The Waukesha Fdry. Co., 340 W. way, has awarded the contract for the construction of a 1-story, 120x300-ft. foundry, to the Federal Bridge & Structure Co. Estimated cost, \$50,000.

WHITEFISH BAY—The city is having plans prepared for the reconstruction of a sewage disposal plant, filter beds of sand and crushed syphons. Estimated cost, \$20,000. Parsons & Orbert, 627 M. & M. Bank Bldg., engr.

Alaska

UNALASKA ISLAND—The Amer. Whale Products Co., 8 South Dearborn St., Chicago, will soon award the contract for the construction of a whale oil plant along Udagak Bay. Plans include refining and fertilizer plants, oil tanks, etc. Estimated cost, \$1,000,000. Woltersdorf & Bernard, 138 North La Salle St., Chicago, archts.

Alberta

ATHABASKA—Mackenzie Basin Fisheries will soon receive bids for the construction of a cannery along Black Bay, here. L. Baxter, Sidney, N. S., engr.

Cuba

HAVANA—The Anglo-Saxon Hospital, c/o Berlin, Swern & Randall, archts., 19 La Salle St., Chicago, is having plans prepared for the construction of a 5-story hospital. A chemical laboratory will be installed in same. Estimated cost, \$600,000.

Ontario

BRANTFORD—The Cockshut Plow Co. will receive bids until Aug. 8 for the construction of a 70x200-ft. foundry and forging building. Estimated cost, \$150,000.

GODERICH—The Town Council is receiving bids for the installation of an automatically controlled chlorinating plant. Mayor Wigle, Chn. of the Committee.

GRIMSBY—The Grimsby Pickle Co. will soon award the contract for the construction of a 3-story, 40x80-ft. pickle factory. Estimated cost, \$40,000.

PETROLEA—The Adams Wagon Co. plans to build a 1-story, 70x200-ft. forge shop and is in the market for equipment for same. Estimated cost, \$25,000.

SUDBURY—The Canada Creosoting Co. plans to build a 1- and 2-story creosoting plant. Creosoting equipment will be installed in same. Estimated cost, \$50,000.

Quebec

MONTREAL—The Canadian Rubber Co., Ltd., Inspector St., has awarded the contract for the construction of a 1-story, 40x50-ft. rubber factory on Notre Dame St., E., to George M. Martin & Co., St. Catherine St., W., Westmount. Estimated cost, \$12,000.

Industrial Notes

CANADIAN ABRASIVES, LTD., has been organized with a capital of \$100,000, and ground has been broken for the erection of a plant which is to cost \$50,000, on Mason St., Victoria. The Provincial Government, through the Department of Industries, has granted the company a loan of \$22,000 at 6 per cent interest. The company will manufacture abrasive papers and powders from natural products. At several points in British Columbia there are extensive deposits of high-grade silica and garnet sands.

WILSON-MAULEN Co., New York City, has appointed S. C. Horn representative for the Cincinnati district, with an office at 311 Commercial Tribune Bldg.

ELECTRIC FURNACE CONSTRUCTION Co., Philadelphia, Pa., announces recent sales of electric furnaces to Lodge, Carrigan & Favorite, of Philadelphia, Pa., and the Electric Steel Products Co., of Turners Falls, Mass.

HAMLIN & MORRISON, Philadelphia, Pa., announce the opening of a branch at 10 East Lexington St., Baltimore, Md., on Aug. 2, 1920, where they will specialize in sampling and weighing. All analytical work will continue to be done at the Philadelphia laboratory.

THE QUIGLEY FURNACE SPECIALTIES Co., New York City, has appointed W. A. Too-

hill sales representative for the Dayton, Ohio, territory. Mr. Too-hill was for some years metallographer with the International Motors Co. at the Plainfield and New Brunswick, N. J., plants of that company.

THE KNOXVILLE IRON & STEEL Co., Knoxville, Tenn., is preparing to use powdered coal for puddling, busheling and reheating furnaces as well as for boilers to replace its present hand-fired method. Contract has been closed with the Quigley Furnace Specialties Co., 26 Cortlandt St., New York City, for a complete system, including coal-milling plant and equipment for distributing and burning the pulverized fuel by the Quigley compressed air system. Work on this installation is to be started immediately.

THE CLEVELAND CRANE & ENGINEERING Co., Wickliffe, Ohio, is publishing a bi-monthly house organ entitled *Crane-ing*. This paper is an intentional effort to create immediate inquiries and subsequent sales for Cleveland cranes, and is a most interesting and well illuminated presentation.

MEIGS, BASSETT & SLAUGHTER, INC., chemical engineer, 210 South 13th St., Philadelphia, Pa., has taken over the interest of Dr. Samuel P. Sadtler in the firm of Samuel P. Sadtler & Son, analytical and research chemist, and has incorporated the same as Samuel P. Sadtler & Son, Inc. Dr. Sadtler is retained as the expert consultant and S. S. Sadtler has been made president, Dr. H. P. Bassett and B. G. Slaughter vice-presidents, and C. C. Meigs secretary and treasurer.

W. S. QUIGLEY, president of the Quigley Furnace Specialties Co., sailed for Europe on the Cunard liner Imperator on July 15. His trip is for the purpose of furthering the business relations of the Quigley organization in England, France, Belgium, Italy and Spain.

THE ANGELUS IRON & RUBBER Co. is installing new equipment in its factory at 1417 N. Main St., Los Angeles, and in the near future expects to begin the production of rubber tubing, stoppers, etc., for the drug and chemical trade of the Pacific Coast. The present output consists chiefly of mechanical goods, especially rubber soles, heels, and valve disks. W. E. McCarty is president and general manager and Emmet Long is factory superintendent.

NEW YORK TESTING LABORATORIES, I. R. Seidell, managing director, has been awarded the contract for the chemical, physical and electrical testing of approximately 400,000 ft. of fire alarm telegraph and police signaling cable and wire by A. E. Roche, engineer, for the City of Troy, the inspection being under the supervision of G. Brinton Jack, Jr., director of inspection and tests.

Manufacturers' Catalogs

THE CUTLER-HAMMER MFG. Co., Milwaukee, Wis., is issuing a new two-color, 24-page booklet on elevator controllers. This booklet, which is known as Publication 840, illustrates the new controllers and emphasizes their simplicity, quiet operation and smooth acceleration. Carbon-to-copper standardized power contacts are used, which are interchangeable on a.c. or d.c. controllers of the same rating. Acceleration is obtained by time limit relays of simple design, which furnish the same comfortable smoothness of acceleration in spite of widely varying load conditions. The last few pages are devoted to auxiliary apparatus for use with elevator controllers, which includes reversing switches, floor selectors, various limit switches, car switches and door switches.

THE GRISCOM-RUSSELL Co., New York City, calls attention to Bull. 1111, entitled "Stratton Air Separator," which tells of the successful removal of water from compressed air.

YARNALL-WARING Co., Philadelphia, Pa., has published a folder description of its Yarway pipe-joint and Yarway holtite pipe clamps. It will gladly furnish copies of the folder upon request.

P. H. & F. M. ROOTS Co., Connersville, Ind., has just received from the press Cat. 68, 2nd edition. This attractive 48-page booklet gives descriptions and illustrations of the many types of blowers for foundry cupolas, steel converters, oil furnaces, gas appliances, filtration and agitation, and also tables of sizes of the blowers.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its 1920 meeting Dec. 27, 1920, to Jan. 1, 1921, at Chicago, Illinois.

AMERICAN CERAMIC SOCIETY will hold its summer meeting at the La Salle Hotel in Chicago, Aug. 16, 17 and 18.

AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Chicago, Sept. 7 to 10 inclusive.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in the Hotel Statler, Cleveland, Ohio, Sept. 30, Oct. 1 and 2.

AMERICAN FOUNDRYMEN'S ASSOCIATION will meet in Columbus, Ohio, Oct. 4 to 8 inclusive.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its one hundred and twenty-second meeting Aug. 20 to Sept. 3, at Lake Superior.

AMERICAN MINING CONGRESS will hold its next convention in Denver Nov. 15.

AMERICAN PEAT SOCIETY will hold its annual meeting at Madison, Wis., Sept. 2, 3 and 4, 1920.

AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

AMERICAN STEEL TREATERS' SOCIETY, Chicago, will hold its second annual convention and exhibit, combined with the convention of the Steel Treating Research Society of Detroit, Mich., in the Coliseum Museum, Philadelphia, Pa., Sept. 14 to 18 inclusive.

ASSOCIATION OF IRON AND STEEL ELECTRICAL ENGINEERS will hold its 14th annual convention at the Hotel Pennsylvania, New York City, Sept. 20 to 24, 1920.

ENGINEERING COUNCIL will hold its next meeting in Chicago, Thursday, Oct. 21, 1920.

INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

IRON AND STEEL INSTITUTE (British) will hold its autumn meeting at Cardiff by invitation of the Ironmasters and Steel Manufacturers of South Wales and Monmouthshire. The date of the meeting will be Tuesday, Sept. 21, for the assembling of the members at Cardiff, and the formal proceedings will open on the morning of Wednesday, Sept. 22.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SIXTH) will be held in the Grand Central Palace, New York City, Sept. 20 to 25.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall national convention at Carnegie Music Hall, Pittsburgh, Pa., Nov. 10, 11 and 12, 1920.

TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its fall meeting at Saratoga Springs, N. Y., Sept. 1, 2 and 3.

New Publications

THE FOREST PRODUCTS LABORATORY, Madison, Wis., announces the following circulars for distribution: Key for the Identification of Native Woods Used for Chairs and Other Furniture; 12 pages and appendix. Glues Used in Airplane Parts; 28 pages, illustrated; report No. 68, prepared for the Naval Advisory Committee for Aeronautics, 1920. The Effect of Kiln Drying on the Strength of Airplane Woods; 69 pages, illustrated; report No. 68, prepared for the Naval Advisory Committee for Aeronautics. Drying Lumber by Means of Superheated Steam; 1 page, with diagram of kiln; reprint from lumber journals. Suitability of Cotton Hull Fiber for Paper Manufacture; 6 pages, 1 chart; reprint from trade journals, April, 1920. Information for Dry Kiln Operators on Drying Hardwoods for Furniture and Similar Products; 14 pages with charts and tables.

THE MELLON INSTITUTE OF INDUSTRIAL RESEARCH of the University of Pittsburgh has issued its seventh annual report on the Industrial Fellowships of the Mellon Institute, by Raymond F. Bacon, director.

Suggesting the Old Divining Rod

THE DESIRE to detect the presence of valuable mineral deposits in the earth without engaging in the arduous and expensive task of digging for them has always appealed to men, whether engaged in mining or not. Knowing that ores and minerals of fabulous value have been located and uncovered by one means or another, it is not surprising that human ingenuity should be requisitioned in an effort to "see into the ground" and thus gain a substantial advantage in locating needed materials and acquiring wealth. Thus we have run the gamut of devices from the divining rod of the charlatan to the more pretentious and reasonable machines for measuring electrical resistance in parts of the earth's crust. The common characteristic of all of them is that they do not "work." That is, no important and valuable mineral bodies, metallic or non-metallic, have been located by their use, save only extensive magnetic surveys to fix the approximate position of large superficial deposits of iron ore.

But hope springs eternal; and where should it be more aspiring than in Germany? Reduced to financial straits and having to rely mainly on economic resources with which to pay her bills and rehabilitate her industries, what more natural than that her subjects should turn to ready means of discovering hitherto unknown mineral deposits within her borders? And since physical exploration takes time and money and offers no certainty of result why not devise means for doing this from the surface and thus steal an economic march on the rest of the world?

Comes now therefore out of Germany "processes and practical means . . . developed to a high state of perfection for definitely locating many mineral and non-mineral deposits in the earth, from above ground." We confess to skepticism. It sounds suspiciously like the "stannophone" which excited so much merriment at the last New York meeting of the A.I.M.E., and by means of which the presence of tin in the earth's crust could be detected by the "cry" of the metal.

But in this case our interest is held and our skepticism perhaps modified by assurance on the part of a responsible investigator that he has "investigated the matter most thoroughly for several weeks," and further, that he has "gone to great pains to have some particular indications of the apparatus checked by borings." We let Mr. HOLZ speak for himself elsewhere in this issue in a letter which he has written from Germany. His opinion and judgment in other matters have been sound and have commanded respect. He has sponsored useful scientific devices well known in the metallurgical world. Whether he has been deceived in this instance remains to be seen, and we shall wait with interest for further developments.

The Engineer And His Thinking

AT THE organizing conference of the Federated American Engineering Societies held in Washington last June one of the speakers referred to "the kind of thinking" of the engineer. Not once, but many times, was the phrase reiterated, in varied form, until it became the theme of the speaker in his argument for the recognition of the engineer, scientist and technologist as a potent but neglected force in public affairs. "It is the engineer's thinking for which he seeks recognition, as well as his works." The phrase is worthy of closer inspection and analysis. What is the engineer's kind of thinking? How does it differentiate him from his fellow citizens; from lawyers, financiers, business men, merchants, clerks, the men on the street? What leads him to do his kind of thinking? And what is, or would be, the value of bringing that kind of thinking to bear on public affairs?

A man's habit of thought is the product principally of his environment of his associations, training and experience. Out of them he acquires a characteristic viewpoint that determines his activities and modifies his opinions. From them he gets his ideas of efficiency, responsibility, fitness, integrity and reliability, all of which affect his usefulness as a citizen as well as his worth in his occupation. Measured by this yardstick let us see what kind of thinking we may expect from the engineer.

His training and education bring him early into contact with the inexorable laws of nature which are the foundation of his later work. With these he may not trifle and yet gain success. No amount of brilliant and clever argument will enable him to ignore the simplest laws of physics and mathematics. If he were not inherently honest he would soon become so or retire as a failure in his profession. Facts must be faced; materials of construction must be used for purposes for which they are best fitted; efficiency must characterize the performance of a machine; analysis must prevail instead of guesswork; tradition must be abandoned in favor of absolute knowledge; reason must prevail and law must be obeyed. The whole preparation of the engineer for his professional work makes him exact, precise, honest, efficient, unshackled by tradition, aggressive in attacking a problem, sound in analysis and judgment, and fearless in execution.

All of these are splendid traits and qualities for citizenship and government as well as engineering. In fact we are beginning to recognize government as a vast engineering undertaking, in which the fitness and integrity of men are fundamental necessities. By his training the engineer will bring a broader mind to bear on public problems than will the lawyer, financier or merchant. He will select men with much the same

care and investigation that he selects materials. He will demand efficiency and good management, because those things are essential to successful business, and government is the greatest business of all. He will excel at organization and management, for these elements are primary in his scheme of things. And when it comes to great public works which are essentially engineering there is no argument as to the necessity for technical control and direction.

The engineer's kind of thinking fits him for almost any position in our scheme of government, unless it be in the judiciary; and even there we have increasing evidence of the need of technical advice. But certainly in the executive and legislative branches of government the engineer can find a widening field for his services. Officials, boards and commissions are in growing need of his advice and counsel. Civilization is becoming more complex, research and investigation are bringing to light things unknown to the non-technical citizen, and government is demanding wider and more comprehensive knowledge. Respect for law and order, which lies at the very basis of the engineer's training, is the imminent need of the world. These are the things for which the engineer's kind of thinking fits him, and to which he can bring a new and valuable force in his capacity as a citizen and government official.

State Ownership of Radium in New York

THERE are several interesting phases to the recent purchase by the State of New York of two and one-quarter grams of radium salt valued at \$225,000. In the first place, it is the first instance in the United States of public purchase and control of a therapeutic agent. But more important, perhaps, it marks the conservation for domestic benefit of a resource that our country was in danger of squandering; New York's supply of radium was produced from carnotite ore mined in Colorado and refined in New Jersey. Further it is an example of public benefaction in the interest of all the people, after years of experiment which demonstrated fully the value to the substance as a cancer cure.

Of the therapeutic value of radium emanations in the treatment of cancer we have no doubt. The testimony of eminent physicians is in accord on that subject, and in the past few years there has been a sufficient quantity of radium available in several hospitals to make experiments in large numbers. Private philanthropy in co-operation with federal agencies was hitherto largely responsible for making available substantial quantities of radium—much more than private practitioners could afford and more in one lot than was collected elsewhere. It has remained for New York, however, to take the step which it has long been evident must be taken by either state or federal governments if the people are to benefit materially and quickly from this great natural resource. And while New York has made the purchase for the benefit of all the people and will extend service gratuitously without regard to state residence, other states should follow her example. It is known that the resources of the United States in radium are limited; and the world's supply, for that matter, is not large. And if all that has been and will be produced were to be applied to scientific and medical purposes, it would still be an expensive substance calling for Government purchase and control. The use of radium in the arts is inconsistent with its value and should be discouraged.

Iron and Steel Export Trade

THERE are various ways of looking upon the matter of iron and steel export trade. The worst way is to consider it a means of relieving ourselves of surplus product, or of "dumping" the tonnage needed to enable the iron- and steel-making industry to operate at capacity, so that the production cost of the entire tonnage may be reduced. "Dumping" was developed by the Germans as a system prior to the war; at no time was it a settled policy of American manufacturers, though to a limited extent it was practiced in a few of the years of the last decade of the nineteenth century. As a rule our iron and steel exports rise and fall much as our production fluctuates, whereas if we were exporting for the purpose of working off surplus product or engaging surplus capacity exports would fluctuate inversely to the fluctuations in domestic demand.

From the national economic standpoint iron and steel exports may be viewed as helping greatly to make up our merchandise trade balance. The iron and steel exports reported for the fiscal year ended last June amounted to \$933,000,000, while our imports of iron and steel, including iron ore, totalled \$39,000,000, showing a favorable balance in iron and steel of about \$900,000,000. In all merchandise our favorable balance was \$2,873,000,000. Thus iron and steel may be said to have contributed almost one-third to the country's trade balance. While the criticism might be made that a favorable merchandise trade balance is not an unalloyed blessing at this time, much the same sort of comparison could have been made in the pre-war years, when the merchandise balance was absolutely essential.

After all, however, the nomenclature of statistics may be productive of misconception. What are "iron and steel exports"? They represent the commodities the Bureau of Foreign and Domestic Commerce has designated as to be included under the heading "iron and steel." There are included such diverse materials as scrap and wire nails, pig iron and enameled bath tubs, rails and typewriters. Now it is perfectly true that typewriters are made chiefly of iron and steel, but these materials also enter largely into the manufacture of passenger automobiles and trucks, which are not returned in the official statistics under iron and steel. Magnetos and transformers are also made chiefly of iron and steel, but they are not reported as such, being included with "electrical machinery and appliances," whereby they take their place, properly enough, with incandescent lamps, batteries, insulated wire and spark plugs.

We exported 553,860 gross tons of steel rails in the last fiscal year, which was certainly quite a tonnage, but the value assigned, \$32,000,000, was just on a par with the value of our exports of gasoline engines and fell short of the value of the steam locomotives exported.

From the economic viewpoint, which is what really counts, it makes a great difference whether an exported commodity represents largely minerals which are of low value in the exporting country but of high value in the importing country or represents chiefly the product of labor. A common view is that we ought to export the products of our labor and keep our mineral resources for ourselves, but it is quite unsafe to generalize. We have trillions of tons of coal in the ground and Italy has practically none. Why should we be indisposed to sell coal to Italy, but, on the other hand, sell to Italy

annually millions of dollars' worth of engines and typewriters? The essence of international trade is that of exchange. We should export what we can produce most readily, whether it is a rail or a typewriter, and import what we find it most difficult to produce. Rails and typewriters are totally different things, even though the statistics put them both in as "iron and steel."

Courts of Law Err

Through Lack of Knowledge

INSIDIOUS pleadings by lawyers in chemical patent cases and consequent decisions by misled judges are establishing mal-traditions which will work many wrongs in future cases. It is now said that "analogy defenses to novelty are substantially excluded in chemical cases."

A review of several cases shows that the courts hold that "reasoning by analogy in a complex field like chemistry is very much more restricted than in a simple field like mechanics"; that "chemistry is essentially an experimental science and that chemical prevision is as impossible today as it was in former times"; that "in chemistry you almost entirely fail to predicate the result—it is a mere question of result from experiment." Another court submits that "a machine which consists of a combination of devices is the subject of invention, and its effects may be calculated *a priori*; while a discovery of a new substance by means of chemical combinations of known materials is empirical, and discovered by experiment." Still another states that "analogy does not go a long way in chemistry."

Chemistry is an exact science and the field is quite readily predictable. The judges are confusing chemistry with the cookery practiced by the old alchemists. Were this attitude of the courts correct, the manufacturer of synthetic nitric acid, for instance, might hold patents for all reactions his product undergoes with other compounds, although easily predicted through the action of nitric acid made from Chilean saltpeter. The great mass of development work done in recent years is based on prediction by the research chemist.

Surely our modern scientists will not stand idly by while the judiciary calmly classifies present-day chemistry with the alchemy of the obscure ages, and through decision based on tradition brings disaster to important industries.

Materials Handling

Section of the A.S.M.E.

LAST week the initial meeting of the Materials Handling Section of the American Society of Mechanical Engineers was held in New York. ROBERT M. GATES, who has been most active in organizing the Section, stated that it must be a bureau of information—complete in its scope, specific in its knowledge of the physical and economic conditions and unbiased in its conclusions. This is to be done by having special meetings on particular subjects, meetings jointly with other sections, other organizations or associations, by taking part in all local and national problems relating to the purpose of the Section.

An invitation has been extended by Mr. ROTH to the Section to take over the Materials Handling Symposium to be held at the Chemical Exposition on the twenty-second of next month. In doing this the Section will perform its greatest function in bringing to-

gether the men who design the equipment and those who use it. F. M. FEIKER, in his address before the Section, emphasized the fact that it was not an interdiscussion among the engineers themselves on materials handling that was needed but the propagation of the best thought on these problems throughout industry. To do this in the chemically controlled industries, in our opinion, the Section can find no better medium than the Symposium to be held at the Exposition.

Considerable discussion was brought forth on what the scope of the programs should be. Some thought the limit should be set at studying the broad, underlying principles, some believed the matter should be taken up in the smallest details, and others thought the human element should be considered the center about which everything revolved. There is no doubt that materials handling embodies a problem having numerous factors and disregard of any one of them is apt to give bad results. However, it is probable that these factors will have to be pulled loose, picked apart and studied individually before any comprehension of the composite whole can be had.

In Support of the

Chemists' Club Library

LIBRARIES are the hallmarks of culture in our modern civilization, evidences of enlightenment, badges of learning, signs of national appreciation of art and literature. Among cultivated people they are supported with scrupulous care; under bolshevism, on the other hand, we are told, libraries are the first public institutions to suffer neglect and abandonment. The comment is significant.

Some time ago we raised our voice in the interest of libraries as important factors in the industrial development of cities and the regions surrounding them. Our reference at that time was particularly to the western part of the United States, but it applies with equal force to the East. Accordingly we are glad to lend our support to the appeal of the Chemists' Club library in New York City for funds with which to enlarge and extend its service to the chemically controlled industries of this country, and particularly in the metropolitan district.

There is no adequate measure of the value of a first-class complete chemical library, and aside from that of the Chemists' Club there is none in the United States worthy of the name. The Club is the logical custodian of such a library, and the industries in the metropolitan district are equally the logical beneficiaries of it if they will make use of it. It is estimated that 35 per cent of the chemical industries of the United States are located within commuting distance of New York, and it is inconceivable that their work can be conducted efficiently and profitably without the aid of the best library that it is possible to bring together. Only those who use a library constantly can realize how it supplements the laboratory and the plant. As evidence of the service which a complete chemical library can render, it is cited that the German Reichsanstalt, before the war, was able to answer directly from the literature about 80 per cent of the industrial problems submitted to it. The cost doubtless was insignificant in comparison with the expense that would have been involved in duplicating researches and investigations that had already been made. In urging the chemical industries to respond to the appeal of the Chemists' Club, we feel that we are presenting an opportunity for service to themselves.

Readers' Views and Comments

Is Synthetic Petroleum Possible?

To the Editor of Chemical & Metallurgical Engineering

SIR:—Of the many great problems now confronting the world probably none is greater than that of providing a bountiful and cheap supply of petroleum. The petroleum of the United States is now rapidly approaching exhaustion. What supplies may be hidden in the other parts of the world are as yet unknown, but in any event the cost of petroleum to the people of the United States must necessarily increase and go very much beyond that heretofore experienced. Sir E. Mackay Edgar last spring predicted that in ten years the United States would be buying from England 500,000,000 bbl. of oil annually. If this should occur the price to be paid would certainly be \$10 or more a barrel, which would make the price paid by our people a fabulous sum.

When it is known that petroleum is composed of approximately 80 per cent carbon and 20 per cent hydrogen, also the ease and cheapness with which these elementary substances can be procured, one naturally considers the possibility of producing petroleum synthetically from those elementary substances. In the belief that man is capable of so handling elementary materials as to form or produce any product that Nature has produced by the association of elements, the problem of the production of petroleum does not seem to be insurmountable.

To solve successfully the problem of the synthetic production of petroleum it is, of course, necessary that we have a starting point. The labor and time necessary for the accomplishment of the feat will be shortened by a thorough investigation of Nature's method. In the oil shales of Colorado, Wyoming and a number of our Western states it is conceivable that we have a starting point for this investigation. We have reasons for believing that the shale as removed from the earth does not contain petroleum, this product being produced by application of heat to the rock. Evidently Nature has so associated the carbon and hydrogen within the rock that the simple act of heating will cause their union in such manner and proportions as to produce petroleum.

There are throughout the United States many chemists who unquestionably would devote study to this problem if it were properly brought to their attention. Many of them have never seen a sample of oil shale nor are they situated so they can procure samples, but should the U. S. Bureau of Mines distribute liberal samples of the oil shale among chemists of the United States, with the suggestion that they endeavor to solve this all-important problem, it is not beyond the bounds of probability that within a very short period this question of the future supply of petroleum would be solved to the immense benefit of the American people.

Many suggestions are now being made that a substitute for gasoline be found. Much attention is also being devoted to the extraction of petroleum from our great deposits of oil shale in the Western states. The Government itself is devoting much attention to these

important subjects, but should this problem of the synthetic formation of petroleum be successfully solved in a thoroughly commercial manner all of these vexing questions would be settled. In fact, the results attained might extend beyond the fields we ordinarily consider as those belonging to petroleum. It is not at all visionary to believe in the possibility of causing carbon, from any of the many sources from which it can be obtained, to combine with hydrogen and create petroleum at sufficiently low cost and in sufficient abundance to be used as a liquid fuel. Such a fuel would use our carbon supplies in a much more economical manner than is now being practiced, as for instance where it is burned under a boiler for the generation of steam for power production with a loss averaging more than 85 per cent of the fuel value of the coal.

New York, N. Y.

EDWARD G. ACHESON.

Post-War Progress in Germany

To the Editor of Chemical & Metallurgical Engineering

SIR:—A careful survey of the metallurgical, chemical and electrical engineering progress in Germany during the past six years shows nothing new of importance to the U. S. A. The large manufacturing plants and research laboratories had to concentrate during that period entirely on war work and on the creation of substitutes for materials which were not obtainable on account of the blockade.

Nearly all the substitutes which were developed, mostly by the chemical industry, are of no value in peace times, especially since the cost of producing them is higher than the world market value of the genuine article. In some rare cases, where the real product can be purchased only in foreign countries and the substitute is manufactured in Germany at approximately the same price, the tendency still prevails to give the preference to the domestic substitutes, because Germany is forced to keep down to a minimum her importations and her payments to other nations.

An example of this kind is the paper textile industry, which was created during the war and is still quite active. Burlap from India ceased to come in soon after the beginning of the war in 1914, and millions of bags were sorely needed for the transport and storage of cement, sand and all kinds of products. Germany is still producing bags of paper thread and of a mixed burlap and paper thread that looks very much like the real article but does not stand the wear and tear of burlap, especially when moist. I do not believe that such paper bags or the German paper twine would ever be used in America. However, the German paper industry produces very nice rugs, colored in all shades and patterns, wall covering, table covers, window shades and similar articles, artistically decorated, very cheap and sanitary, perfectly satisfactory for the purpose. This industry may outlive the return of normal times.

Another industry which has come to stay in Germany is the manufacture of synthetic ammonia by the Haber process, the only one which permits the economical production of this material independent of the necessity

of cheap electric power. The large German aniline concerns are even at present increasing the capacity of their ammonia plants, not only in order to make Germany independent of foreign sources but especially to be able to export the material and to help pay the big bill.

Wonderful progress—entirely independent of war work—has recently been made in Germany in the utilization of physical forces about which theory still knows very little.

Processes and practical means have been developed to a high state of perfection for definitely locating many mineral and non-mineral deposits (ores, coal, salts, oil, gases, water, etc.) in the earth, from above ground, for accurately determining the position, depth, width and thickness of each such deposit, and for differentiating between the various materials forming the deposit.

The last named feature is of utmost importance; thus if the apparatus is adjusted for lead it is acted upon only by lead, and by nothing else and the number of materials it can be adjusted for amounts to over 100 and is constantly being increased.

Thoroughly practical and reliable apparatus has been developed for this purpose and is already being used with wonderful success in central Europe. Since very little gold is in the treasury of the new German Republic all the payments of billions of marks we hear so much about have to be made in coal, potash, metals and other contents of the earth.

The apparatus mentioned offers unlimited possibilities for locating new fields of mineral deposits and shifts the responsibility onto the laborer to get the stuff out of the German ground, which is full of valuable material. Very large deposits of oil, potash, coal, asbestos, etc., are present in Germany, the majority entirely untouched, and as a matter of fact they will not be touched until Germany knows definitely the amount of the bill it has to pay.

I have investigated the matter most thoroughly for several weeks and have gone to great pains to have some particular indications of the apparatus checked by borings. I have worked with the apparatus personally for quite a time and have also investigated the excellent work the inventor and his staff is doing right along for many prominent mining concerns and the government railroads.

What interests Americans much more than the results of these activities in Germany is the economic importance of such an invention to the United States. Certainly it should be carefully investigated by some governmental agency, and if what seems to be its everyday performance can be transplanted over the ocean, when in the hands of an ordinary field party, then the invention should be acquired by the United States Government.

The entire country could be surveyed, under the joint supervision of the United States Bureau of Mines and the United States Geological Survey, and the United States Government could then grant licenses to operating companies on a royalty basis.

If a practical working arrangement between the United States Government and the operators can be established—and there is no reason why this should not be the case—the financial returns to the Treasury would of course be immense.

HERMAN A. HOLZ.

Berlin, Germany.

Phosphate and Manganese Production in the Society Islands

Phosphate is the only mineral produced in or exported from the Society Islands. It is produced and exported by one company, the Compagnie Française des Phosphates, a French corporation with head offices in Paris, and with a capital stock formerly of 5,000,000 francs, all French owned, except for a relatively small amount held in Tahiti. The capital stock is now 11,000,000 francs. This concern, organized in 1908, has the exclusive mineral rights of the island of Makatea, which is about 120 miles north of Tahiti and has an area of roughly 1,200 acres. Two piers about 300 m. long, a part of which length, however, is on shore, have been constructed. Mooring buoys and lighters are used by the loading vessels.

MINING PROCESS IS SIMPLE

The phosphate, as exported, is virtually the soil itself, which is dug with pick and shovel and loaded on cars on a short narrow gage railway and drawn to the works, where it is put through crushing and drying processes. It is sold on a moisture percentage basis. After going through the drying process the product is stored in bins awaiting shipment. Most of the machinery used is of French manufacture.

At the present time nearly all the phosphate is exported to New Zealand. Before the war much of it went to San Francisco, some to Europe, particularly France, and a considerable quantity to Honolulu. It is expected that in the future the product will recover the markets of the pre-war period.

PHOSPHATE PRODUCTION

The phosphate soil shipped runs about 80 per cent phosphate, according to the statement of the manager of the company. Before the war the annual production was from 80,000 to 90,000 metric tons. In 1919 the production was approximately 40,000 metric tons, and it is reasonable to expect that the production will rapidly increase.

LABOR PROBLEM RESTRICTS PRODUCTION

The great difficulty encountered in this enterprise, as in all enterprises in this colony, is the difficulty of procuring suitable labor. At present the company employs about 500 workmen and employees, many of whom are Japanese. The French Government has recently enacted a decree providing for the importation of foreign labor, and fixing the conditions of such importation. It remains to be seen whether it will prove profitable to import such labor under the conditions prescribed but the probabilities are that it will, at least for the phosphate company.

MANGANESE INVESTIGATIONS UNDER WAY

There is one island in the group which is known to contain manganese deposits. The owner of the mineral rights has engaged engineers to make an exhaustive investigation, and within the next three or four months it will probably be definitely determined whether there is manganese on this island in paying quantities and whether it can be profitably mined and exported. As matters stand now it is purely a matter of speculation as to whether manganese will be a commercial factor in the colony.

Decennial Celebration Forest Products Laboratory

An Account of the Two-Day Meeting at Madison Celebrating the Decennial Anniversary of the U. S. Forest Products Laboratory—Greater Co-operation on the Part of Industry Asked—National Forest Problems Discussed

EXTENSIVE conservation of our national wealth of wood through more efficient utilization was the keynote sounded throughout the decennial celebration at the Forest Products Laboratory at Madison, Wis., July 22-23. More than 200 visitors from all parts of the country were present, representing every line of wood-using industry, including fifty-nine wood-using associations and companies, eighteen lumber manufacturing associations and companies, the deans of twelve forestry schools, the United States Forest Service, and other visitors and friends. They came to pay tribute to the laboratory's ten-year record of service to American industry.

The opening session of the gathering convened in Agricultural Hall at 10 o'clock on the morning of July 22. H. F. Weiss was chairman. The program of addresses included Mr. Weiss's introductory remarks; "Legislative Measures for Forest Conservation," by Governor Philipp; "Translating Knowledge Into Power," by President Birge of the University of Wisconsin, and "The Forest Products Laboratory," by C. P. Winslow, present director of that institution.

After luncheon the program continued with inspection of the work and exhibits of the laboratory. Guides in charge of small parties showed the visitors the various lines of endeavor in which the laboratory is saving millions of dollars a year to the people of the country. Following the inspection trip was a period for recreation consisting of automobile tours around the city, boat rides, and swimming.

Nearly 500 prominent lumbermen, manufacturers and users of forest products, and members of the Forest Products Laboratory attended the banquet in the evening. Burr W. Jones presided as toastmaster. Lieutenant-Colonel W. B. Greeley, Chief Forester of the United

States, spoke on "Forests and National Prosperity." Following the address of Colonel Greeley, Max Mason, research specialist of the National Council of Defense, gave an illustrated talk explaining in detail the submarine detector which he perfected during the war and which was successfully used in European waters.

At the Friday morning session John Foley, forester for the Pennsylvania Railroad, was chairman, introducing the speakers as follows: D. C. Everest, secretary and general manager Marathon Paper Mills Co., "Some Problems of the Pulp and Paper Industry"; H. E. Howe, chairman research extension division National Research Council, "America's Place in Industrial Research"; and W. A. Gilchrist, representing the National Lumber Manufacturers' Association, on "Some Problems of the Lumber Industry."

MR. WEISS URGES GREATER CO-OPERATION

"The tendency of the time, I think, particularly on the part of Government and industry, is for these two to work too much apart, this being due largely to a lack of familiarity with each other," said H. F. Weiss, chairman of the opening session, in his introductory remarks. "I believe it is particularly necessary for the Government and the industries to co-operate more wholeheartedly if our country is to play a prominent part in the commerce of the world. In the Forest Products Laboratory the Government has established an institution which is doing much direct good for all of the wood-using industries and indirectly is doing good for all of us, because all of us use wood in some form or other."

Mr. Weiss then introduced the first speaker of the morning, Governor Philipp of Wisconsin.

"Nature would have been a great conservator of

forests if she had permitted trees to grow square rather than round," declared Governor Philipp during his reminiscences of the wasteful methods of the earlier days of the lumber industry.

"It is unfortunate for the country and unfortunate for the timber supply of the country that there was not some control even back in the '60s and '70s, when the great timber supply was here, that there was not some supervision that compelled the use of what we at that time regarded as the class of timber that had no commercial value for purposes to which it could be put and save the high-grade timber—the timber that we need so much today—for the future. But somehow our forefathers did not foresee it. We will not blame them."

REFORESTATION A NATIONAL PROBLEM

Concerning an advisable policy of reforestation Governor Philipp said: "This state has had some experience in reforestation. We have attempted, and we have made an honest attempt, to replant some of our cut-over timberlands. Now I have this to say about it. As a state policy it is not a possible thing today.

"The cost of the land, the cost of planting, the cost of the care that the plant needs, the taxes that the state loses provided it reserves this land for forestry purposes, make the price, if we compute it up to the time that the trees might become merchantable, so high as to make it an impracticable thing. Nor is it, in my judgment, a state duty. Let us assume that the state of

cause we at one time had a forest, and that those states that at one time had forests should now undertake this great business proposition, this great speculative investment, in order that the whole country might have a timber supply. That does not appeal to me. It is not a state duty, it is a national duty. "The National Government should recognize it promptly and take hold of the future supply in an efficient manner. The timber supply of the future, the one which is produced, should be the supply of the entire country, and whatever it costs should be the expenditure of all of the people."

PURPOSE OF FOREST PRODUCTS LABORATORY

President Birge of the University of Wisconsin emphasized in his remarks the fact that during the last few decades the need had become apparent for a different type of institution, of which the Forest Products Laboratory is an excellent example. The speaker developed the idea that this organization is engaged in assimilating vast stores of technical knowledge accumulated to such an extent that no one man can grasp it all; and of translating these stores of knowledge into power that energizes industry and enables greater things to be done by better and less expensive methods.

Director C. P. Winslow, in speaking of the purposes and work of the laboratory, illustrated the manifold uses of wood in connection with the everyday life of the people. He brought out the great problems of conservation and utilization of forests, of cut lumber and of

SPEAKERS AND EXECUTIVE COMMITTEE

Wisconsin would plant in the northern part of our state a million acres of young pine. I do not know what it would cost to do it, nor does anyone else know. The best we could do is to make an estimate which would be liable to be wrong, but we would have to wait at least fifty years before we could get any merchantable timber. Now when that timber comes into the market it is not for the state of Wisconsin alone. If it were it would not be a supply for the country, and what we need is a supply for the whole nation. So then those who agitate that the state ought to undertake reforestation would do it upon the basis that it is a state duty merely be-

finished product. He stated that it was the broad purpose of the Forest Products Laboratory to aid the nation in solving these problems.

He said in part: "The Forest Products Laboratory is called an institution of industrial research. Its object is to acquire, disseminate and apply useful knowledge of the properties, uses, and methods of utilization of all forest products. This is a broad field of almost unlimited scope—the surface has as yet been but partially scratched."

Mr. Winslow gave statistics showing by conservative estimate that the work of the Forest Products Labora-

tory effected an annual increase in production and decrease in waste aggregating \$30,000,000. These figures, the speaker said, should prove the value and importance of industrial research.

In concluding, Mr. Winslow indicated the immense program of work yet to be undertaken by the laboratory, saying: "The Forest Products Laboratory is the only institution of organized research engaged upon the problems of these industries, and those problems yet untouched and unexplored are many and of far reaching importance. What, for example, of the possibilities which may result from the development of permanently durable and water-proof glues or adhesives and their application to the use of material too small or of too poor a grade for other service—what of their application to forest economics through the increased value thus given to small second growth material? What of the sulphite pulp liquor problem involving the possibility of utilizing the 55 per cent of the wood fed into the pulp digesters and now lost in the waste sulphite liquors? What of the problems of packing, boxing, and crating of various materials and commodities for shipment and transportation when conservative estimates show a possible theoretical annual saving to the country of \$300,000,000? What of the need for improvement and the method of treatment and handling of piling and dock timbers in water infested with marine borers which destroy the piling within eighteen months after placement and cause an annual replacement aggregating millions of dollars in the various harbors of the nation? What of the waning supply of hardwoods and the need for authentic knowledge of the properties of South American and other foreign woods as compared to those of our own country for which they may ultimately be needed as substitutes?"

CONSERVE AND GROW MORE FOREST PRODUCTS

Lieutenant-Colonel Greeley contrasted the extensive and often wasteful use of wood in this country with the frugality and care with which France conserves her very limited supply of lumber, and he praised the industry and foresight of a people who could build up within an area less than that of our largest state the great industrial nation that France is today.

"The lesson which such things brings home is, in a broad way, the same fundamental truth which underlies many economic problems of the present time—not alone those of America but of the whole world as it strives to get back to normal industry. It is an old and simple axiom. Aside from the will to work which is the foremost quality of any strong nation, its economic and social progress depends in the long run upon the foresight and efficiency with which its natural resources are used."

The speaker showed by statistics the extensive use to which wood has been put in this country and the urgent need of a yet greater supply—the need on the farm, in building houses, in our paper industry, on our railroads, in boxing and crating our commodities, and in our factories.

He spoke also of the diminishing supply of wood, stating that three-fifths of the original supply of timber in the United States is gone and that every year we are taking out of our forests four times the amount of wood that we are growing in them. Moreover, the availability of the remaining timber is rapidly becoming less. Half of the remaining timber of continental United States, Colonel Greeley says, is in the three states bor-

dering the Pacific Ocean. And the true index of timber depletion is not the quantity that is left but its availability.

Colonel Greeley indicated the reason for our decreasing wood supply and the cure for it as follows: "The real cause of our timber depletion is idle forest land. The area of idle or largely idle land is being increased by from three to four million acres annually as the cutting and burning of forests continue. The enormous area of forest land in the United States not required for any other economic use, estimated at four hundred sixty-three million acres, would provide an ample supply of wood if it were kept productive. Depletion has resulted not from using our timber resources but from failure to use our timber-growing land.

"The answer to the forestry problem of the United States is not to use less wood but to grow more—to put our idle acres of burned and logged-off timber land at work growing trees. This is not inherently a difficult thing to accomplish. It is not the Utopian dream of a technical enthusiast. Three-fourths of it lies in preventing forest fires. But it does require an aggressive national policy of reforestation. It requires concerted action by the national and state governments to do the things which must be done by public agencies. It requires the active participation of the private forest owner. It requires a clear definition of public and private responsibilities as to timber-growing land, with an equitable showing of the cost. There is no phase of our whole problem of an assured and perpetual supply of timber that cannot be met by simple and obvious measures once the constructive effort and capacity for organized co-operation of the American people are put behind them."

GREATER SUPPORT NEEDED

"If the Forest Products Laboratory is to be of the greatest possible assistance to the pulp and paper industry closer co-operation must exist with the mills, for the final test of any laboratory trial must take place in the mill," remarked Mr. Everest, in discussing several problems of the pulp and paper industry. "Too often information vital to the successful prosecution of a problem is withheld or full and hearty co-operation is lacking. If the mills refuse to give the laboratory their full confidence and at the same time maintain a critical and unsympathetic attitude but little real progress can be made on those problems in which the industry is vitally interested. If, however, they look upon the laboratory as a part of their own organization and treat it as such, correcting its mistakes and commending its successes, the greater portion of any research problem is already solved."

Mr. Everest spoke of the valuable assistance the laboratory is rendering in solving the manifold difficulties confronting the pulp and paper men in these days of decreasing supply of timber and increasing price of labor and the appliances of manufacturers. He believed that inadequate support was being given.

In conclusion he said: "We need this laboratory. Private enterprise cannot buy such facilities and conditions. You who have been privileged to see and know what is being done here must realize that if we are to solve our technical problems relating to timber, its care, perpetuation and proper use we must back this laboratory to the limit, either by inducing Congress to adequately provide for it or by individual subscriptions if necessary."

Prevention of Fires and Explosions in Coal-Tar Chemical Works*

BY NICHOLAS RICHARDSON†

THE problems for the fire prevention engineer in chemical works, and particularly in the synthetic dye industry, are new, peculiar and difficult, and it does not appear that expert chemical directors or advisers give sufficient attention to the accidents that may occur even in well-thought-out processes due to numerous causes which sometimes are foreign to the purely chemical nature of the operation. To one who has had opportunities of observing a wide range of operations and has particularly noted accidents occurring in many processes that were considered non-hazardous by men of experience, many features present themselves that are lost sight of by the man who has concentrated on a few lines only. Although a process may be non-hazardous in its normal operation, failure of mechanical devices to function properly, and unforeseen irregularity in the materials used, may result in hazardous conditions not contemplated.

The following remarks are quite apart from a question of insurance rate, or underwriting considerations, and attempt only to suggest lines on which may be worked out arrangements for reducing to a minimum the losses and interruption of business that may ensue from accidents in the particular operations. The most important is a rigid policy of so detaching and isolating all integral parts that the loss or damage in one will be localized and will not cause the interruption of production of the plant as a whole.

GENERAL DESIGN OF PLANT

Plant to be in units, each as small as practicable, separated and isolated from each other as efficiently as possible.

The vital points of the plant to be located in areas of absolute safety. The boiler and power plant, ice-making or refrigerating plant, the research laboratory with valuable records and the storehouse, where large amounts of finished products may be stored, are points of chief concern.

The location of processes shown to be especially hazardous to be considered with reference to other considerable values in plant and materials.

The location of above-ground tanks containing large quantities of flammable liquids to be considered with regard to the flow of liquid possible from leakage, rupture, etc. When tanks must be near buildings the consequences of falling walls should be considered.

GENERAL TYPE OF CONSTRUCTION

Buildings should be one story in height, and preferably of fire-resistive construction. It must be remembered that non-combustible construction does not necessarily imply fire-resistive qualities, and unprotected steel may have less fire-resistive quality than heavy timber.

The minimum of wall openings is recommended where separate buildings expose each other—blank walls are the most desirable—and necessary doorways should be protected with efficient fire doors.

The peculiar conditions of certain production buildings point to the advisability of light roofs, except over fusion kettles, etc.

In general it is recommended that the power plant, ice plant, research laboratory, fusion building and drying building be of strictly fire-resistive construction throughout; nitrating buildings, sulphonating buildings and grinding buildings to have fire-resistive walls and light non-combustible roofs, and other buildings to be of as good type of construction as the business warrants, slow burning wood construction for buildings where there are no manufacturing processes not being particularly undesirable.

OTHER POINTS TO BE CONSIDERED IN THE DESIGN OF A COAL-TAR CHEMICAL PLANT

In all buildings where benzol or toluol is used in any way, the floors should be above the surrounding ground level, without hollows or pits of any kind, and have ample ventilation openings at floor level to the outside. The vapors of these hydrocarbons are about three times as heavy as air and do not readily mix with moisture in the atmosphere. Floors of course should be of concrete, asphalt or some similar material. Such buildings must not be located in proximity to other buildings or plant where direct heat or flame is present, and the approach of locomotives must be avoided.

The floors of buildings where azo compounds may be present should be so adequately drained that the collection and drying out of dangerous salts is impossible.

The arrangement of storage tanks for benzol, toluol, fuel oil and other flammable liquids should be carefully considered. The most desirable arrangement is to have all storage below ground. Where above ground, the units should be of as limited capacity as practicable and dikes provided to confine escaping liquid from overflow, rupture, etc., to safeguard buildings, other tanks, wharves, etc., also to conserve the liquids themselves.

Gravity flow into buildings should be avoided.

Where air pressure lifting is necessarily used, the pressure egg should preferably be outside.

Heating arrangements for dealing with frozen benzol should be carefully designed to preclude the possibility of overheating.

Consideration should be given to safeguarding tanks containing flammable liquids against lightning.

The disposition of empty benzol or toluol drums which contain vapors should be considered.

The disposition of tank cars containing flammable materials is very important; the location of sidings where they are discharged or allowed to remain must be considered with regard to damageable property; the record of accidents with tank cars is very bad and too much care cannot be exercised in their use.

SPECIAL FEATURES IN MANUFACTURING

Nitrating. Nitrating benzol, toluol and other organic compounds is a very hazardous process; there are two important points of interest:

The first is the flammable nature of the material used. The vapors of benzol and toluol are heavy and have a considerable explosive range in mixtures with air; ignition is possible from many causes, among which are overheating, electrical power or lighting apparatus, static electrical discharges, and all may be guarded against.

The second is the danger of accident in the actual

*From a report submitted by the Underwriters' Bureau of New England to the Atlantic Dyestuff Co., Boston, Mass.

†Watertown, Mass., Arsenal.

nitration reactions, since failure of temperature control, stirring devices or regulations of flow of materials may have results that are of explosive violence, possibly followed by fire, difficult to control.

Nitrating, therefore, should be carried on in small buildings well away from other parts of the plant and be of non-combustible construction, but designed so that any explosion may be dissipated with a minimum of damage and the loss and interruption of work localized. All nitrating products must be considered as potentially dangerous. While the lower nitrated products may be considered safer than those of a higher degree of nitration, they cannot be considered safe, and in event of a fire even from an extraneous cause, conditions might arise from which explosion or uncontrollable fire would ensue.

Sulphonation. Sulphonation has dangers allied to the above and also due to material that may be treated. In case sulphonators need to be heated, indirect heat in all cases should be adopted; if direct heat from gas, fuel oil or other means is unavoidable, arrangements should preclude possibility of unequal heating and burning through.

Autoclaves. When processes involving use of autoclaves, with heat and great pressure, are used, autoclaves should be in special fire-resistive buildings, or at least in fire-resistive sections, properly cut off from other parts of the building. The dangers of accident with such apparatus have been shown to be great. When certain materials are treated the result of even a trifling accident may be disastrous.

Fusion. In this process, ignition of the contents of fusion kettles frequently occurs, and such apparatus should be in buildings of non-combustible construction.

Drying. Vacuum driers are at all times the most desirable, but where drying is done at atmospheric pressure, driers should be entirely of metal, or non-combustible material, and wooden trays or racks and paper should not be used in them. Drying buildings may often contain high values in nearly finished dyes, when a small fire from any cause may result in great loss of stock.

Grinding. In this operation there is often great hazard; dust may cause an explosive atmospheric condition, and possible igniting causes are many, such as foreign material, electric sparks, etc.; particularly is there danger at the end of a run. Some dyes may heat up in the mill owing to the incompleteness of certain previous reactions, and the grinding of all dyes with picramic acid base is attended with the greatest danger of explosion. Grinding should be done in a separate and small building, each mill should be isolated from others, and it is probable that some form of light non-combustible construction is most desirable.

Distilling. Stills are always liable to accident, and the magnitude of the resultant damage is largely dependent on the material being handled. They should be treated with the same regard to danger as nitrators. Direct fire-heated stills are, relatively, the most dangerous and their use should be avoided, or very rigid precautions taken.

Sulphur Colors. The manufacture of this class of dyes is very dangerous. Nitro and nitroso compounds are used, also sulphur and sulphides, involving the possible production of explosive or spontaneously ignitable substances.

When it is not known exactly what other dyes or intermediates will be manufactured, and also where it

is probable that changes and new processes will continually be introduced, it is recommended that a very careful review of all processes and reactions projected, and all materials used or produced, be given with a view solely to their fire hazards before the processes are put in operation.

Storage of Raw Material and Intermediates. The proper and safe storage of many raw and intermediate materials should have attention. Such compounds as picric acid, picramic acid, nitroso compounds, sulphides, chlorates, alcohol, etc., should each be in separate storages.

A storehouse divided into sections of small area by proper fire walls should allow the segregation of materials which may cause trouble due to careless handling, mixing with others, etc.

The storage of acids in tanks outside probably does not call for special attention, but the disposal of spent mixed acids from the nitration processes is important. Accidents have occurred due to nitrated, or unnitrated material, other than the acids, becoming mixed with them.

GENERAL MANAGEMENT

Accidents due to carelessness of employees are difficult to guard against. Smoking in all production or storage buildings should be rigidly prohibited. Owing to the difficulty of enforcing this rule it is suggested that a smoking room be provided in a safe location in the plant, where employees are even encouraged to go. It is also recommended that detached buildings be provided for locker rooms, and that employees be not allowed to leave their clothes or belongings in manufacturing buildings, or use driers for hanging wet clothing, etc.

Where processes are continuous, and night, Sunday and holiday work is necessary, it is often impossible to have the efficient supervision that obtains during usual day working hours, and records show that accidents are more liable to occur at these times. This is a peculiarity of the industry and has a great bearing on the hazards of the plant as a whole.

The foregoing remarks are largely directed from a prevention attitude, but an efficient system of fire-fighting apparatus, hydrants, and adequate water supply is assumed, in order that localization of fire may be assured.

Silk Production in Japan

The year just ended in May was one of the best for Japan's silk industry, owing to the prosperity in the United States and the lack of supplies from Europe, says the *Japan Times and Mail* for June 7, 1920. The export figures from June, 1919, to May 31, 1920, reached 517,311 bales, an excess of 50,305 bales over the previous year. The previous largest figure was less than 500,000 bales.

The silk production of the country has attained a remarkable development during the past few years, especially during the war period, in which the world's demand for silk yarns was centered on the Japanese market, owing to the decline or stoppage of the sericultural industry in Europe. Though the sudden depression of the business caused by the financial failures toward the closing part of the silk year dealt a severe blow to the trade, the production for the season was still a record.

The Power Problem in a Copper Refinery

An Outline of the Steam Recovery Possible With Waste Heat Boilers and the Steam Demand for Heating Electrolyte, With a Discussion of the Bearing of These Factors Upon the Problem of Choice of a Prime Mover

BY LAWRENCE ADDICKS

AN ELECTROLYTIC copper refinery may obtain its power from a self-contained steam or gas plant, from an adjacent water power or by transmission, but while each case will call for a different type of power plant as far as the provision of current for the tanks is concerned, the demand for fuel for smelting and for steam for heating liquors will remain unchanged. The fact that both fuel and steam are required introduces waste heat boilers in any event and most refineries have steam-driven electrolytic generators, although there are notable exceptions. The conditions surrounding each case call for individual study of all the factors entering and it is the purpose here merely to point out the general requirements and limitations of the problem as a whole.

In the early plants, before the days of waste-heat boilers and with live steam heating, the total water entering the plant could be considered as utilized as roughly one-third for generation of electrolytic power, one-third for steam for heating and miscellaneous uses and one-third for make-up water in the tanks and at the boshes. The ideal steam-driven plant would, therefore, be one where the steam generated by waste heat at the reverberatories would be sufficient to supply the demands of the engine room, the exhaust from the engine room used for heating and the condensate finally used as make-up water at either the boshes or the boilers. This ideal solution is yet far from being reached, but the very uniform conditions of load and output under which a refinery is run have enabled sufficient progress to be made in this direction considerably to handicap hydro-electric and gas plant competition.

WASTE HEAT BOILERS

It is perhaps most logical to start with the consideration of the amount of steam available as a by-product at the reverberatories.

Given a fair grade of bituminous coal, a modern refining furnace will average eight to nine tons of product per ton of coal burned. As there are two furnace operations and as the anode furnace treats about 15 per cent of anode scrap and as various other items contribute to swell the net tonnage treated in either furnace, a ratio of four to one is safe, giving 25 per cent fuel consumption on a cathode basis.

A properly designed boiler, placed close to the throat of the furnace and equipped with an economizer, can be depended upon to give an average equivalent evaporation of between 6 and 7 lb. of water per lb. of coal fired. We, therefore, have available about 1.5 lb. of steam per lb. of cathode output, or in other terms a 200-ton furnace will develop at least 363 boiler horse-power.

The rate of steaming is not uniform, as although the coal in a large modern furnace is consumed quite

steadily throughout the twenty-four hours, the two extremes of poling and charging give large differences in the temperature of the gases leaving the furnace. The situation is graphically expressed in Fig. 1. Where a number of furnaces are feeding boilers in parallel, their operations are usually staggered enough to give a sufficiently uniform steam supply to avoid any serious irregularities in the demand upon the main boiler installation. Where the electrolytic power is obtained by transmission, this variable supply might cause undesirable fluctuations, but in this case most of the steam would be used for heating purposes where considerable

FIG. 1. WASTE HEAT BOILER STEAMING RATE

variations are temporarily permissible. On Sundays the waste heat steam supply is lessened, but so is the miscellaneous demand.

A good general discussion of the whole question of waste heat boiler equipment is given in a paper by Arthur D. Pratt in the *Transactions* of the A.S.M.E. for 1916, vol. 38, p. 599, and of the particular application to copper refining furnaces in an article by Clarence L. Brower in the *Engineering and Mining Journal* for May 22, 1915, vol. 99, p. 892. The secret of successful operation lies in placing the boiler as close as possible to the furnace throat and in the exclusion of air infiltration. A good modern installation obtains a temperature of 1,600

to 1,700 deg. F. in the boiler firebox as against 1,000 to 1,200 deg. in the earlier attempts. The exit gases may be brought down to 500 or 600 deg. F.

ELECTROLYTIC POWER

As has been discussed in a previous article (MET. & CHEM. ENG., March 15, 1917), the power required in the tank house depends upon the current density and the temperature of the electrolyte. In average practice the density will be around 18 amp. per sq.ft. and the temperature about 130 deg. F., in which case the power con-

FIG. 2. WATER RATE PER KW.-HR. ON 1,200 KW. UNIT

sumption will approximate 350 kw.-hr. per ton of copper deposited. In general a refinery with a capacity of 100,000 tons a year may be considered large enough to be a thoroughly economical unit and this would call for a dependable power capacity of about 4,000 kw. Whatever type of steam-driven prime mover be adopted, a thoroughly modern power plant of this size should deliver a kw.-hr. at the switchboard for not over 15 lb. of steam, given reasonable superheat and vacuum and excluding auxiliaries. We, therefore, require at the throttle roughly 2.6 lb. of steam per lb. of copper refined, or nearly double the 1.5 lb. available from the waste heat boilers.

CHOICE OF PRIME MOVER

In cases where water power is cheaper than steam at the place where a refinery has been located, generally for reasons quite apart from the cost of power, it is of course employed, and we have such a case in the refinery at Great Falls, Mont. In the same way transmitted power originating at a water power is used at Tacoma and to a certain extent at Baltimore. A very unusual instance of power transmitted from a steam generating plant is that of the electrolytic department of the leaching plant at Chuquicamata, Chile. In general a refinery is located with reference to copper freights rather than cost of power and in most locations steam power is cheaper than water power.

Gas power has also been more or less discussed, but up to the present time nowhere applied to copper-refin-

ing work as far as power generation is concerned. The great first cost of the installation and its low economy at partial loads have always been handicaps. The history of refineries has been that they are continually being added to and expanded and that even individual units are seldom operated under the conditions for which they are designed, while above all else a gas plant lacks elasticity. On a basis of thermal efficiency some very interesting figures may be worked up, but very large steam turbine units can now practically equal these.

As between steam turbines and reciprocating engines, the question is largely a question of size of unit. A turbine can expand steam down to the highest attainable vacuum without unreasonable increase in size and owing to its high rotative speed very large units can be built in small compass. In the case of a reciprocating engine the speed is limited by valve gear considerations, while cylinders larger in diameter than 54 in. are undesirable and the practical limit of size is about 72 in. diameter by 72 in. stroke. The low pressure cylinder is frequently divided into two in making a four-cylinder triple-expansion unit. These considerations bring us to about 2,000 hp. discharging into 27½ in. vacuum as a reasonable limit size of unit for a reciprocating engine and the steam economy attainable

FIG. 3. APPROXIMATE STEAM TURBINE WATER RATE

is indicated in Fig. 2. A turbine of this size can hardly equal this performance even with higher vacuum and when the efficiencies of conversion from alternating to direct current are included it is under a serious handicap as far as economy of steam consumption is concerned. In larger sizes, however, the turbine reaches very high economy. Fig. 3 shows approximately what water rate may be expected with 170 lb. gage pressure, 100 deg. F. superheat, 28½ in. vacuum, after allowing 7 per cent loss of a.c.-d.c. conversion. (See Stott, quoted below.)

The advantages of a turbine are based partly upon its compactness and its ability to utilize high superheat and vacuum. One inch of vacuum or 50 deg. F. superheat will vary the water rate 5 or 6 per cent in a high pressure turbine. As to the space factor, it must be remembered that its value is considerably less at a refinery than in a city power house and regarding condensation the cost of producing high vacuum must not be lost sight of. The temperature of saturated steam drops very rapidly as vacuum increases and if cold water is not available the cost of circulating water may become very great. These conditions are illustrated by the curves in Fig. 4.

The whole question of the relative value of the several types of prime mover is reviewed by Stott, Pigott and Gorsuch in *Transactions, A.I.E.E.*, vol. 33, p. 1,133. The special application to electrolytic work was discussed at a joint meeting of three of the engineering societies several years ago and may be referred to in the various transactions as follows: Newbury, *Trans., A.I.E.E.*, vol. 33, p. 1; Longwell, *Journal, A.S.M.E.*, July, 1914; Addicks, *Trans., A.E.S.*, vol. 25, p. 65. In a general way it can be stated that with cheap coal the plant will be steam driven, using reciprocating engines if small and turbo-alternators distributing through rotary converters if large. With expensive coal, a fairly large plant and regular tonnage a gas plant could be made to pay. With water power close at hand it would probably displace either steam or gas.

THE ELECTRIC GENERATOR

The tank house circuits demand (a) direct current, (b) high amperage, (c) low voltage and (d) wide voltage range. The amperage used has steadily increased as the generator builders have found it possible to build larger capacity commutators and to-day runs between 10,000 and 15,000 amp. per circuit. The voltage is generally limited to 200 volts or less per circuit and the maximum unit to be considered is, therefore, 3,000 kw., while 10,000 amp. at 120 volts or 1,200 kw. would more nearly represent present practice. A 1,200-kw. generator, direct connected to a reciprocating engine, would call for 1,900 i.hp., which is about the limiting engine size.

The generator problem is almost wholly one of commutation. This subject is reviewed at length under the heading of "Physical Limitations in D.C. Commutating Machinery," by B. C. Lamme, *Transactions, A.I.E.E.*, vol. 34, p. 1,739. The simplest case is that of the direct connected reciprocating engine. Here the slow engine speed, certainly not over 125 r.p.m., permits reasonable freedom in commutator design, and the volts per segment, length of bar and amperes per brush arm can all be placed at conservative figures. It must be remembered that steady duty at 100 per cent current load and occasionally at abnormally low voltages imposes commutating conditions far more severe than met with in average practice and that any roughening of the commutator surface becomes rapidly worse. Commutating pole field construction has made a great advance toward sparkless commutation in all electrolytic generators.

The efficiency of a direct connected engine type generator exclusive of bearing friction will be about 94 per cent and the e.hp. delivered by the generator should be about 88 per cent of the i.hp. of the engine. The total losses on a 750 kw. C-W. generator built in 1905 are given in Table I.

The direct current steam turbine has also given satis-

Volts	Volts	125	125	100
Current	Amperes	0	6,000	9,500
Output	Kw.	0	750	950
Bearing friction	Watts	4,000	4,000	4,000
Windage	Watts	1,600	1,600	1,600
Brush friction	Watts	6,200	6,200	6,200
Core and pole losses	Watts	18,000	18,500	15,000
Field copper	Watts	6,560	7,930	4,680
Armature copper	Watts		11,750	29,400
Brush resistance losses	Watts		8,650	15,400
Total losses	Watts	36,360	58,630	76,280
Mechanical losses	per cent input	32.4	1.5	1.1
Magnetic losses	per cent input	49.4	2.3	1.5
Electrical losses	per cent input	18.2	3.5	5.0
Output (efficiency)	per cent input	0	92.7	92.4
Load	per cent rating		100	127

faction in service, although there is a practical limit to the size of commutator which can be constructed, as it is necessary to restrict the diameter owing to the high rotative speeds required. A two-cylinder compound driving a direct connected generator and exhausting into a direct-current turbine connected electrically in parallel makes a satisfactory unit and several such pairs are in successful operation. The steam economies

FIG. 4. WATER REQUIRED FOR CONDENSING

possible with such combinations are indicated in Fig. 2. This same field is covered by geared units, a rather high-speed generator being geared to a rather low-speed turbine. For large plants electrical rather than mechanical connection between turbine and generator, as provided by rotaries, has many advantages.

The unipolar generator which delivers direct current without a commutator and which may be driven at turbine speeds is a very pretty theoretical solution of the whole problem. Practically, while commercial units have been built (see Lamme, *Transactions, A.I.E.E.*, vol. 31, p. 1,811), many special problems are involved

in the collection of the current, and this type of apparatus has not received any considerable application.

If a turbo alternator is used as the main source of current, allowance must be made for the efficiency of the distributing system, the transformers, conductors and rotary converters absorbing about 7 per cent of the a.c. output.

The voltage regulation should be made wide and is satisfactorily accomplished by hand control. In the case of reciprocating engines the speed may be altered so as to keep the engine operating at the best cut-off. This, however, means some adjustable attachment to the engine governor, which has its drawbacks. With ordinary direct current generators, either engine or motor driven, the usual hand rheostat gives satisfactory voltage control and modern commutating pole generators will operate well at surprisingly low voltages. In the case of rotary converters it is necessary to use booster control on the alternating current side, which may be supplemented by employing multi-tap transformers.

A circuit of 120 volts would probably have 360 tanks connected in series and when drawing copper two groups of, say, thirty-six tanks each might be cut out. This would call for a 20 per cent cut in the normal operating voltage during this period. On the other hand, while a tank house is supposed to be operated on a constant current basis, this is very apt to become constant wattage, the current density being temporarily increased during periods of low voltage.

HEATING ELECTROLYTE

Heating the electrolyte has already been discussed (MET. & CHEM. ENG., March 15, 1917). At what temperature it will pay to carry the liquor must be determined for each case. Eastern refineries expend about 0.75 lb. of steam per lb. of copper produced to raise this temperature, say, 30 deg. F. This means a power saving at the generator of 15 per cent taking an overall temperature coefficient of 0.5 per cent per deg. F. If we are using 3.0 lb. of steam (including auxiliaries) per lb. of copper at the engines the saving will be 0.45 lb. as against 0.75 lb. required at the heating coils and it is evident that live steam heating would not pay. If we run an electrolytic unit non-condensing it will take about 4.0 lb. of steam instead of 3.0. If we are able to run a proper proportion of the circuits non-condensing we can, therefore, furnish steam for heating the tanks and obtain an average overall steam rate of 3.2 lb. on 85 per cent of the original resistance, or 2.7 lb. per lb. of copper instead of 3.0 when running without heating.

Where the electrolytic power is hydraulic live steam heating may not pay if there is not waste heat boiler capacity in excess of other needs, but except where very high densities are employed, thereby predicated clean bullion and resulting in considerable electrical heat being generated in the tanks, it generally is desirable to heat the electrolyte from purely metallurgical considerations.

The condensate from heating coils is generally collected for use in washing the anodes and cathodes free from alimes, bluestone crystals, etc., and a small amount of heat is in this way returned to the system as well as a safeguard established against leaky heating coils withdrawing any electrolyte and sending it to the sewer.

The silver refinery and the purifying system or bluestone plant will always require a certain amount of boiling or evaporating. This varies greatly in amount

in different plants. In a very general way it may be stated that there will be 2 lb. of steam condensed for every pound of water evaporated and that about 10 per cent of the total steam used will be employed in this way in the average plant.

Steam siphons used for pumping are really heaters. their efficiency as pumps running but a few hundredths of 1 per cent. The steam consumption of a siphon depends upon the original design and upon the amount of nozzle wear at the time of test, but 1 per cent dilution of the liquor is probable and 3 per cent possible.

HEATING FEED WATER

The steady full load conditions of the electrolytic engines call for a complete installation of economizers. Probably 10 per cent of the steam furnished by the boilers will be called for as exhaust steam for further heating of the feedwater.

MISCELLANEOUS DEMAND

There is a considerable amount of pumping to be done, such as circulating electrolyte, circulating bosh water, supplying condensers, fire system, general water supply, feeding boilers and high pressure system for hydraulic cylinders. There is a more or less extensive compressed air system for operating copper hoists and pneumatic tools. There is power required for the motor drives of cranes, shop tools, ventilating fans, sampling drills and possibly an electric railway. Finally there is the lighting system.

If steam driven, non-condensing, in a large plant, these various units will consume from one-third to one-half as much steam as is called for by the electrolytic generators operated condensing. This steam may advantageously be turned into the heating systems, the requirements of which it roughly fills, turning all of the electrolytic exhaust into the condenser. Another solution is to electric drive all auxiliaries and supply the current by means of a non-condensing light and power unit. There is even the opportunity of utilizing an electrolytic spare for this service, thereby reducing the total equipment called for, the plant consisting of several electrolytic generators, one light and power unit and one spare for both services.

SUMMARY

The total steam consumption of a copper refinery will vary within wide limits, depending upon the size of

TABLE II		lb. steam per lb. copper.
A.	Electrolytic power, condensing	2.5 to 3.0
B.	Light, power, water, air and auxiliaries, non-condensing	1.0 to 1.5
C.	Evaporating, live steam	0.5 to 2.0
D.	Heating, exhaust steam	1.0 to 1.5
E.	Total steam demand, $A + B + C + D$	5.0 to 8.0
F.	Exhaust steam for D from B	1.0 to 1.5
G.	Contributed by waste heat boilers	1.5 to 1.5
H.	Net steam demand, $E - (F + G)$	2.5 to 5.0

plant, the current density employed and the amount of purifying of the electrolyte required, and may be stated somewhat as in Table II.

China's Soap Trade

Although many small native soap factories, producing cheap and inferior soaps from local raw materials, have recently sprung up in various parts of China, for many years there has been an increase in China's import trade in this commodity as a result of the growing use of soaps by the Chinese.

Forest Products of the Northwest as Industrial Chemical Assets

By R. K. STRONG

AT PRESENT the great industry of the Pacific Northwest is that of lumbering. One-fifth of the standing timber of the United States is in Oregon, and consists mainly of Douglas fir. The byproducts of this industry form a large potential source of raw materials for the industrial chemist.

It is a matter of considerable expense to dispose of the waste wood and sawdust produced at the sawmills. Within the last few months one concern has put into operation a 90-foot incinerator, said to have cost \$50,000 to erect. Except near the cities, most mills burn the waste in this way, to prevent its accumulation forming a nuisance. In the forest the stumps are difficult to remove on account of their immense size and the length of time required for decay. The trimmings of the trees form a considerable fire hazard.

WASTE WOOD UTILIZATION

In the cities much of the waste wood is used as domestic fuel. An appreciable percentage of the sawdust and least valuable waste is utilized in this way for the production of power. Three large plants in Portland use such fuel in the generation of electricity. A large paper mill is being constructed in which much fuel will be obtained from a neighboring lumber mill, in return for which electricity is furnished the latter.

In considering the chemical uses to which waste wood may be put two lines of procedure are available—namely, those in which the material must be dried at some stage in the process, and those in which the waste is utilized by wet methods. On account of the large moisture content, which may be over half the gross weight, and the difficulty and expense involved in removing the same it would seem that processes operating without the necessity of removing the water would be more likely to succeed if other considerations were even approximately equal.

METHODS INVOLVING VOLATILIZATION OF WATER

As a fuel, wood waste and sawdust have inherent drawbacks, such as the high moisture content mentioned above and the low calorific value when dry. It is stated that the fuel value of a cord of wood on the dry basis is 20 per cent less than that of a ton of coal. The combustion space is necessarily larger and the flame temperature lower than with coal. In spite of these disadvantages the fuel gives satisfaction for steam generation. Plants for the production of fuel gas from wood are in operation, and it is expected that more will be installed.

Considerable work has been done on the destructive distillation of Douglas fir. As it has not yet proved successful on a large scale, probably on account of the low yield of valuable products, the problem is open.

WET METHODS

The wet methods available for treating wood waste center around the production of paper pulp and seem to offer every promise of ultimate success, if attacked with the proper scientific and financial backing. Either with or without preliminary steam distillation for the recovery of the turpentine content, the wood can be made into a satisfactory pulp for certain grades of

paper by the soda or sulphate process. Experiments here have shown a high cellulose content in Douglas fir. The Forest Products Laboratory, at Madison, Wis., states the yield, in experiments made there, to be 1,170 lb. of bone dry, screened, unbleached pulp per 100 solid cubic feet of wood—the equivalent of one cord as ordinarily piled. The report states further that the fiber is of good length and the kraft pulp of good grade, with uses similar to that made of white spruce.

An approximate idea of the amount of pulp it is possible to recover from waste wood may be obtained from the statement that about 25,000 cords of waste wood, not including sawdust, are produced per month on the harbor front of Portland alone—a location which offers excellent facilities for utilization of this material both as to quantity available and transportation advantages. Even if only half of this were used, a production of 5,000 tons of paper pulp per month could be obtained.

Another wet process is that by which wood sugar is made for use in the manufacture of ethyl alcohol. Considerable importance attaches to this product in regard to its use as a fuel for internal combustion engines. Canada is attacking the problem in a large way.

OTHER WOOD PROBLEMS

Minor problems that are worthy of study and full of promise are the extraction of tannin from the bark of the Western hemlock and the Douglas fir, and the recovery of rosin and turpentine from forest waste and stumps. Douglas fir pitch is receiving attention as a source of turpentine and rosin oil, the pitch being drawn from pockets caused by wind shakes.

PAPER PULP

The amount of paper pulp at present produced in the Pacific Coast region is relatively small, although the mills already established are intelligently operated and of good size. From the latest statistics of the Forest Service, for the year 1918, the following figures are cited to compare and contrast the production of paper pulp in the Eastern and Western states:

EASTERN STATES			WESTERN STATES		
State	Cords Pulp Wood Consumed	Per Cent of Total in U. S.	State	Cords Pulp Wood Consumed	Per Cent of Total in U. S.
Maine.....	1,235,000	23.5	Oregon.....	240,000	4.6
New York.....	1,004,000	19.1	Washington.....		
Wisconsin.....	861,000	16.4	California.....		
Pennsylvania.....	384,000	7.3			
New Hampshire.....	345,000	6.6			
		72.9			4.6

Total consumed in the United States, 5,251,000 cords.

The output of the Pacific Northwest should be greatly increased and the percentage raised to an appreciably large fraction of the production of the country. This could be done with more benefit to the country and at less expense than the proposed utilization of the Alaskan forests for this purpose. Not that the latter is undesirable, but that the former can be more easily and quickly accomplished.

Research and development would make possible the use of other woods of the region besides those at present made into pulp. With 46 per cent of the standing timber of the United States in the Pacific Northwest and an abundant supply of water for power and pulp treatment, there should be a paper-producing industry in this region ranking with that in any other part of the country. Research and capital can accomplish this in a reasonable time.

Zones of Weakness in Solidified Ingots

BY LESLIE AITCHISON, D.MET.

IN THE course of a considerable experience of the defects which are met by engineers in bars, forgings and castings made of steel and other metals I have been convinced that a very considerable proportion of these defects can be traced back to the earliest history of the metal; namely, to the form which it assumes immediately after it has been melted and poured from the melting furnace. In other words, it can be said quite definitely that a very large number of the engineer's problems are created for him in the steel or brass ingot which provides the metal which he finally uses. This being so, it seems desirable to give a brief account, as far as possible, of some phenomena associated with the production of metal ingots.

Columnar crystals will fill up the whole of an ingot if the supply of fluid metal does not fail or if the growing crystals do not meet any solid obstruction. The first requisite means that the metal in the ingot must remain liquid for a comparatively long time. In practice it may happen in relatively small ingots that the steel in the center of the ingot remains fluid to the end, but in large ingots this very rarely occurs, and the center of the ingot is cooled down to the freezing point before the columnar crystals have grown right across the ingot. The solidification of the remaining metal takes place from a large number of independent centers, the result being that the center of the ingot is filled up with numerous small crystals of no special shape and whose axes do not lie in any definite direction in relation to the walls of the ingot mold. These may be termed "free" crystals. The main variation among the different steel ingots is the proportion of the columnar and "free" crystals found therein. From what has been said above one important factor which determines the proportion of these crystals is evidently the temperature from which the metal was cast, as this will fix the time during which the steel will remain fluid after casting.

SETS OF CRYSTALS DISTINCT AND SEPARATE

The structure of the cross-section of an ingot shows the way in which two sets of columnar crystals growing from adjacent sides of the ingot mold interfere along a plane of junction. It is quite clear that the two sets of crystals are quite distinct and separate and that even where they touch they do not join or coalesce. If the junction has been suitably magnified for examination the nature of the junction is made much more plain and it is evident that really there is no junction at all, there being rather a complete discontinuity or hiatus between the two sets of crystals. If this is so it may be expected that between the individual columnar crystals (which after all have formed their junctions in exactly the same way in which the junction of the sets of columnar crystals has been formed) there will be no real coalescence. Similarly there will be a zone in which the columnar crystals of the outside of the ingot join onto the free crystals of the core, and here again there will be distinct discontinuity or lack of cohesion between the two constituent types of crystal.

It must be stated that in the majority of cases the crystal boundaries, particularly those of the columnar crystals, are defined by a layer of non-metallic impurities—slag or sulphides or the like. Conversely it may

be put that if there is a layer or a pocket of non-metallic material in the ingot it will result in a greater or less degree of discontinuity between the crystals around which it is formed.

POSITION OF NON-METALLIC IMPURITIES PREORDAINED

In the middle of the ingot—i.e., in the free crystals of the core—there are found a certain number of places at which there are inclusions of non-metallic impurities. It can easily be understood that these inclusions will occur somewhere, and a little thought will show that the positions in which they are found are more or less preordained. As the steel rises in the mold the steel in contact with the sides and bottom freezes first and the succeeding layers of steel to solidify will be more or less cup shaped. Owing to fluid contraction and to the contraction which occurs during the plastic state of the metal in the core of the ingot there is a tendency for the steel of any particular layer to sink in the middle to a level rather lower than that at the sides, so that a layer which was originally horizontal becomes at a later stage more or less sharply depressed in the middle. The result is that the successive layers of steel as they solidify are distorted downward. The non-metallic inclusions will follow the same path, so that the region filled with free crystals—i.e., the part of the steel which was fluid longest—contains these inclusions arranged symmetrically pointing downward and inward toward the central axis of the ingot. Since the inclusions are there it is safe to assume that there is some discontinuity between the crystals at these points.

SUMMARY

Summing up, it is evident that in the solidified ingot there are certain definite zones in which there is only very moderate cohesion between the crystals of the steel, and consequently that these positions in the ingot are zones of weakness. The zones in particular are: (1) the junction of each columnar crystal with its neighbors. (2) The junction of each set of columnar crystals. (3) The junctions of the columnar and the free crystals. (4) The symmetrically placed "herringbone" arrangement of planes of non-metallic impurities lying on either side of the axis of the ingot. These four places, since they represent the weakest zones of the ingot, are the positions at which contraction is likely to take effect. The result of the contraction will be the pulling apart of the hotter crystals within the ingot from each other and from the cooler, more rigid and stable shell, thus producing contraction or cavities in the metal. The pulling apart of the columnar crystals either individually or in sets may easily occur in the early stages of the contraction—i.e., during the later stages of solidification—while the later contraction will become evident in the junction of the columnar and free crystals and in the "herringbone" cavities within the free crystals.

Unfavorable Outlook for German Potash Industry

The issue of *Deutsche Allgemeine Zeitung* for June 16, 1920, says that at the general meeting of the Bergbau-Aktien-Gesellschaft Justus in Volpriehausen the chairman remarked that domestic sales had come to a complete standstill. No exports are being made to the United States at present. Negotiations with the Americans are still pending, but the Potash Syndicate expects to come to a satisfactory settlement and to resume deliveries in the near future.

Studies in Evaporator Design*—II

The Effect of Temperature Drop and Temperature Level on Heat Transmission in Vertical Tube Evaporators—Corrections for Hydrostatic Head—Boiling Points, Heat Drops and Steam Temperatures as Factors†

BY W. L. BADGER AND P. W. SHEPARD

DETAILS of the methods used in conducting the tests and making the measurements have been given in Part I.

Pressures were measured in mm., temperatures in deg. C., and heat in kilogram calories. Where condensed water was weighed, it was weighed in pounds. When measured, it was calculated directly in kilograms. Heating surface was calculated on the basis of the wet surfaces. Both top and bottom tube sheets were included. The heating surface in tubes was 65.4 per cent of the total, the rest being in the basket shell.

Heat input was taken as the sum of the latent heat at the temperature calculated from the pressure of the steam basket, and the sensible heat recovered between this temperature and the temperature of the condensate. All calculations from the simplest up were made independently by two persons and checked back. All figures in the calculations were carried to 0.01 deg. for temperatures, 0.1 mm. for pressures, 0.1 kg. for weights and 0.1 cal. for heat. The final results were rounded off to the nearest even digit for K .

RESULTS

The essential data for the three series of experiments are given in Tables II, III and IV and in Fig. 3. It will be noted in the tables that the results are averaged in groups. In Fig. 3 the average of each group is indicated by a large circle. These circles have their centers at the exact points indicated in the averages and their radius is fifty units on the scale for K . This is an arbitrary choice, but is thought that it represents approximately the accuracy of the averages. At any rate there are few cases where it is possible to suppose that the average has a greater accuracy than this.

The principal thing which the curves indicate at once is the decided effect of both temperature level and temperature drop. The curves cannot be represented by a simple equation and it has not been thought worth while to try to derive any expression for them, in view of the limited significance of the absolute numerical values.

The large number of determinations on the 25 deg. point on the 75 deg. curve is due to the fact that this point is common to several sets of investigations now under way. The theoretical work of the station has been interrupted at numerous times. After each interruption this point was redetermined in order to be certain that the evaporator was in a condition similar to that under which the other runs had been made. No definite explanation can be made now for the fact that the 20 deg. point on the 75 deg. curve is low.

In order to get a basis for more general comparisons, these figures were all corrected for hydrostatic head.

The points corrected were not the averages actually determined, but were read off the smooth curves. The method of recalculation is illustrated by the following example:

Let t_s = temperature of steam (calculated from pressure).
 t_w = temperature of boiling liquid at the surface (calculated from vacuum).
 t_b = temperature of boiling liquid at the bottom tube sheet.
 $\theta_1 = t_s - t_w$ = temperature difference at surface = "apparent" temperature drop.

$\theta_2 = t_s - t_b$ = temperature difference at bottom.

$\theta_{mh} = \frac{\theta_1 + \theta_2}{2}$ = mean temperature difference corrected for hydrostatic head.

P_s = absolute pressure in vapor space.

P_h = head of liquid on bottom tube sheet in mm. mercury.

$P_b = P_s + P_h$ = total pressure at bottom tube sheet.

For example, take the 25 deg. point on the 75 deg. curve.

$P_s = 287.6$ mm. $t_w = 74.89$ deg.

$t_s = t_w + 25.00$ deg. = 99.89 deg.

$\theta_1 = 25.00$ deg.

The hydrostatic head is 48 in. of water at a temperature of about 75 deg. (sp. gr. of water at 75 deg. = 0.9749).

$P_h = \frac{48 \times 25.40}{13.6} \times 0.9749 = 87.4$ mm.

$P_b = 287.6 + 87.4 = 375.0$ mm., $t_b = 81.37$ deg.

$\theta_2 = 99.89 - 81.37 = 18.52$ deg.

$\theta_{mh} = \frac{18.52 + 25.00}{2} = 21.76$ deg.

Now from the curve we read the apparent K at $\theta_1 = 25.00$ deg. as 2,240.

Then the corrected K is $2,240 \times \frac{25.00}{21.76} = 2,573$ cal.

The complete data from such calculations are given in Tables V, VI and VII and are plotted in Fig. 4, to which the curves for apparent K are added for comparison.

NOTES ON CALCULATIONS

This method of calculation calls for boiling points higher than steam temperature for the 5 deg. and 10 deg. points on the 60 deg. curve and for the 5 deg. point on the 75 deg. curve. These cases were handled as follows: The point on the basket where the boiling point of the liquid should become equal to the temperature of the steam was determined. At this point, then, the true temperature difference should be zero so far as any boiling is concerned. The mean temperature difference over the part of the heating surface used for boiling was taken as the arithmetical mean of zero and the temperature difference at the top. Assuming that the heating surface below this point was totally inactive, the apparent values for K were recalculated on the basis of the new temperature drop and the diminished heating surface. For the sake of comparison this correction was also made on the basis of temperature drop only, neglecting any consideration of decreased heating surface. Both values so obtained are plotted for each of the three points in question.

It will be seen that neither assumption was correct, but that the truth lies somewhere between the two. The values calculated on the basis of no action in the lower part of the heating surface are too high, thus

*Read before the American Institute of Chemical Engineers, Montreal, June 27, 1920.

showing that there is some heat transmitted below the point where theoretically there is no temperature difference between boiling liquid and steam. On the other hand, heat transmission in this area cannot be as high as during boiling, for the values calculated on the basis of the whole heating surface are far too low. Evidently, then, there is some action in the lower part of the basket in heating liquid from the temperature in the down-take (which is that corresponding to the vacuum, or a little below because of radiation and incoming feed) to temperatures approaching steam temperature. Since heat transmission from steam to non-boiling water is known to be at a far lower rate than heat transmission from steam to boiling water, this furnishes a qualitative explanation for the difference in results from the two assumptions. It has not been considered worth while to try to draw any quantitative results from these considerations.

It should be noted that the corrected coefficients change very little with change in temperature drop. What slope these lines have is undoubtedly due to the factor of increased circulation pointed out by Claassen (see above). It will also be noted that these corrected curves differ from each other nearly as much with

changes in boiling point as do the apparent values for K. Many reasons for this will suggest themselves such as increased density of steam, decreased viscosity of boiling liquid, decreased viscosity (and consequently better drainage) of condensed water, better thermal conductivity of condensed water, etc. The authors at present have no definite explanation to offer as to the cause of this increase in heat transmission with increase in boiling point.

Another interesting fact is that at higher temperature levels both the apparent and the corrected curves are becoming parallel.

The hydrostatic head corrections furnish a ready explanation for the fact that the apparent values for K approach zero as the temperature drop approaches zero.

As the apparent temperature drop (θ_a) approaches zero, this means that t_w approaches t_s . As t_w approaches t_s , the distance below the top tube sheet where $t_b = t_s$ approaches zero. Hence the inactive part of the heating surface approaches the whole heating surface, and the total heat transmitted approaches zero. But since in calculating the apparent heat transmission coefficient the whole heating surface is used, it is evident that the coefficient must therefore also approach zero as the heat transmitted decreases.

RELATION OF STEAM TEMPERATURE TO HEAT TRANSMISSION

If a section is taken across the curves of Fig. 3 at right angles to the X-axis, one obtains a curve showing the combined effect of increased steam temperature and increased boiling point for the same temperature drop. Such sections taken for temperature drops in multiples of 5 deg. are plotted in Fig. 5. These curves are obviously developing a fairly definite limiting curve to the left, but will extend out to fill the whole space to the right. Fig. 5 furnishes an excellent explanation for the very wide variations in Kerr's results both experimental (Bull. 149, La. Agr. Exp. Sta., p. 33) and on the commercial scale. (Trans., A. I. M. E., vol. 30, p. 67.) Kerr plots K against steam temperature without any regard to temperature drop and then attempts to derive a single equation to cover all these points. Our results show how completely false it is to assume such an expression.

On the basis of his experimental results, Kerr develops an equation, $U = 225 + 17,500D$, where $D =$

FIG. 3. RELATION BETWEEN APPARENT HEAT TRANSMISSION COEFFICIENT AND TEMPERATURE DROP FOR DIFFERENT BOILING POINTS

steam density in lb. per cu.ft. In attempting to plot this equation, it was found that the equation called for such high values of K that they came entirely off our chart. To make Kerr's figure for steam at 130 deg. check with our figure for steam at 130 deg. and the 30 deg. temperature drop, his results, as calculated and converted to metric units, are multiplied by 0.302. The resulting values are plotted in Fig. 5.

Parr (Engineering, vol. 121, p. 146) has suggested for multiple effect evaporators, $U = 300\sqrt{PD}$, where P is the absolute pressure of the heating steam in lb. per sq.in. and D is the density of steam in lb. per cu.ft. Parr's equation is derived from theoretical considerations and not from experimental data.* Values calculated from this expression and converted to metric units are also plotted in Fig. 5. These results and those of

Kerr are reproduced here merely to illustrate how impossible it is to represent heat transmission over a range of values for either boiling point, steam temperature or temperature drop by any expression which does not involve at least two of these three factors.

It will be seen by a comparison of the corrected values for K and the apparent values for K that one part of the cause for low coefficients in the latter bodies of multiple effect evaporators is accounted for by the effect of hydrostatic head. Of the many factors which affect heat transmission coefficients, hydrostatic head is the one which is susceptible of calculation. The authors believe that if values reported in the literature for heat transmission coefficients had been uniformly corrected for hydrostatic head, the results would be found much more concurrent and systematic than they have been thought to be. As work progresses in the evaporator experiment station and more data are accumulated on both apparent and corrected heat transmission coefficients over a wider range of conditions, it seems not unreasonable to expect that the choice of the coefficient for the different bodies of the multiple effect may not be such a difficult matter in the end. Removing the factor of hydrostatic head may remove much of the uncertainty regarding heat transmission coefficients at low boiling temperatures or low temperature drops.

CONCLUSIONS

The following conclusions for the present must be taken as indicating tendencies only and must be applied with caution to evaporators which differ very much in design from the evaporator in which they were determined:

1. The apparent coefficient of heat transmission in

vertical tube evaporators decreases in temperature drop and approaches zero for zero temperature drop.

2. The apparent coefficient of heat transmission increases with boiling point for a given temperature drop (which also means increasing steam temperature).

3. Correcting the apparent heat transmission coefficients for hydrostatic head gives figures which change but little with temperature drop. This remaining

FIG. 5. VARIATIONS IN HEAT TRANSMISSION WITH STEAM TEMPERATURE, FOR VARIOUS TEMPERATURE DROPS

change is probably due to increased circulation at increased rates of boiling.

4. The corrected heat transmission coefficients used show considerable differences as the boiling point is increased and the temperature drop held constant.

5. It is impossible to represent heat transmission coefficients for different boiling points, different temperature drops and different steam temperatures by any expression which does not consider at least two of these three factors.

New Zealand Prohibits Exportation of Adulterated Kauri Gum

The New Zealand Government published in the *New Zealand Gazette* of May 27, 1920, an order in council prohibiting the exportation of kauri gum which has been in any manner adulterated or mixed with other gum.

Legal Notes

BY WELLINGTON GUSTIN

Decree Against Continental Sugar Co. Modified— Byproduct Plant Is Abandoned

In a recent decision of the Supreme Court of Michigan the Continental Sugar Co. and the United Engineering Co. were defendants. The sugar company operates a plant at Blissfield, Lenawee County, Mich., for the manufacture of beet sugar. Among its waste products was a liquid known as Steffens water, which developed an offensive odor and could not be run into the river there, and this it was compelled to store at some expense. The United Engineering Co. believed that by a process of evaporation this waste product could be converted into a valuable byproduct, and entered into an agreement with the sugar company, whereby the engineering company agreed to install a plant for such purpose at its own expense on a part of the sugar company's premises, the net profits to be divided between them. This contract was to cover a period of ten years from October, 1917. The sugar company had the option to purchase at any time after three years.

The engineering company let the job of constructing and installing the plant to J. C. Carland & Co. The plant was completed and operated for a few months, but was then closed because its operation was not profitable. Payment for its services having been made by the engineering company, Carland & Co. sought to foreclose its lien upon the plant against the two companies. The trial court gave a decree against the companies and found the amount due to be a "lien upon said refining or potash plant, equipment and appurtenances and leasehold rights."

The Supreme Court upheld this decree except it provides that should the purchaser, at a sale of the property, remove the buildings, the premises should be restored to substantially the same condition as before the construction of the plant. This modification of the decree was obtained upon the appeal of the Continental Sugar Co., one of the defendants.

How a Loosely-Drawn Contract Caused Loss to Glue Manufacturer

Interesting facts on how loosely business is sometimes conducted are brought out in the action of the Oscar Schlegel Manufacturing Co. against Peter Cooper's Glue Factory; so also is the law applying to a sales contract to furnish one with chemical requirements covering a period.

The plaintiff was a jobber exclusively, handling glues, wax, paints and chemicals. It bought only for retailing to the trade and did not manufacture or use any of these articles in its own business. The defendant glue factory wrote plaintiff, stating that it had been instructed by one of its officers to enter contract of said jobber "for your requirements of special BB glue for the year 1916, price to be 9c. per pound. . . . delivery to be made to you as per your orders during the year." This writing, together with the jobbers' written acceptance thereof, was held by the court to show that there existed a valid contract between

the parties. The parties admitted these writings constituted the only agreement between them, but defendant claimed that it lacked mutual promises and therefore was unenforceable when it sought to avoid deliveries.

DEFENDANT REFUSES DELIVERY

It appears that the parties entered upon performance of the agreement and deliveries were made from time to time amounting to 169,800 lb. Between October and December, 1916, the jobber ordered 79,891 lb. of glue, to meet its requirements, but defendant refused to deliver the same. The jobber in anticipation of the performance of this contract on the manufacturer's part had sold 42,000 lb. of this glue, and as it could no longer be bought in the open market it lost its profits on such sales. Other damages sustained by refusal to perform on part of defendant brought plaintiff jobber's damages up to \$6,431.28, for which it recovered a judgment.

The jobber filled the orders of its customers as it received them by calling upon the factory to deliver the goods under the contract. Therefore the jobber's requirements for the year 1916, in special BB glue, were the amounts of orders received therefor from its customers to whom its salesmen had sold such goods.

SYSTEM WAS THE USUAL ONE

This method of doing business, and the meaning of the term "requirements" as used in the contract, were concededly well known to the manufacturer, which had done business with the jobber under the same system as far back as 1910. The contract for 1915 was also for the jobber's "requirements" of special bookbinder's glue, for the balance of the year from March 3, 1915, at a fixed price quoted. No question arose as to the meaning of this contract, nor, said the court, did any question arise as to the meaning or validity of the contract for the year 1916, until the price for this special glue rose so high that the contract became very valuable to the jobber, and entailed a corresponding loss of profit to the manufacturer which it could have made by selling elsewhere. The contract price was 9c. per pound, and, by December, 1916, prices were quoted as high as 25c.

Under these conditions the jobber sought to reap a legitimate advantage from its contract, and by soliciting the trade received orders for the last three months of 1916 aggregating 126,100 lb. Instead of repudiating the contract, the manufacturer undertook to place an arbitrary limitation upon the same, by saying it would give the jobber 10 per cent more than it had purchased in 1915, or about 40,000 lb. But despite this the manufacturer never notified the jobber to cease taking orders from its customers for delivery of this glue, nor did it ever notify the jobber that it would not live up to its contract.

MANUFACTURER COULD HAVE PROTECTED HIMSELF

The manufacturer had not protected himself against any abnormal variation in price during the year, nor had he limited the amount to be furnished. The only proviso in the contract which he cared to insert was that the contract was contingent upon fires, strikes, accidents and other causes beyond the control of the parties. A rising market, says the court, could have been guarded against by the factory, by inserting in the contract a clause fixing the maximum amount which

the plaintiff might be entitled to receive thereunder, but instead the manufacturer made an absolute contract at a fixed price for the entire year to deliver as much glue as the jobber might be able to sell.

CONTRACT WAS MUTUAL, SAYS COURT

As for the contract not being mutual, the facts are that if the jobber had taken orders for this quality of glue, and had failed to buy the amount to fill such orders from the defendant, the latter could have held the jobber under the contract and recovered the damages which it sustained by reason of the jobber's failure to order such glue from the defendant. This it could have done, no matter how low the market price might have fallen during the year. The parties entered upon this contract with their eyes open to all the conditions then existing or which might possibly arise, said the court, and with the intention of being mutually bound thereby. The mere uncertainty as to the amount of glue which might be required to be furnished under the contract is no reason why it was not a mutual one, nor does it make the contract unenforceable.

JOBBER HAD RIGHT TO SOLICIT ORDERS

The customers' orders were received by the jobber and transmitted to defendant under the contract. The jobber's good faith in soliciting the orders, and their validity, were not successfully attacked. In the absence of any notification from the manufacturer that it would not or could not fill all its orders, the jobber had a right to proceed legitimately and in good faith to solicit orders from the trade and expect the filling of these orders by the manufacturer. The manufacturer had no right to limit arbitrarily the amount which the jobber should receive under the contract, and it was therefore liable for the damages which the jobber sustained. Thus the Appellate Division of the New York Supreme Court affirmed judgment against the Peter Cooper Glue Factory.

SAME SITUATION IN ANOTHER CASE

In another case the same situation was presented to the New York Court of Appeals. There also the parties had left the contract open and indefinite as to the quantity of the goods the purchaser might order from time to time. The seller had there sought to have the contract reformed, so as to call for only the usual amount of goods sold in the preceding year, as an answer to the buyer's suit for damages sustained by reason of the seller's refusal to furnish the goods called for under its orders for the second year. Here the court said:

"It is quite probable that this controversy originated in a circumstance which the defendant, at least, had not anticipated or provided for. After the execution of the contract there was a large advance in the market price of iron and the manufactured products of iron, and consequently the value and selling price of the goods covered by this contract advanced in the same or possibly in a greater proportion.

"The needs of the plaintiff could be indefinitely enlarged, when the market was in such a condition as to enable it to undersell its competitors in the same business, in consequence of a favorable contract with the manufacturer of the goods. If a party contracts for goods upon a rising market, he is ordinarily entitled to such profits as may accrue to him by reason of a prudent or favorable contract."

Determination of Naphthalene in Crude Naphthalene and Tar

BY JOHN C. PASTRE*

The following rapid and accurate method for determining naphthalene in crude naphthalene and tar was worked out by R. C. Downing, chief chemist, and the author, while endeavoring to determine the yield of naphthalene from our products at the new plant of the Steel & Tube Co. at Indiana Harbor, Ind.

Distil 1,000 g. of tar into two receivers, collecting in the first receiver all the distillate up to 270 deg. C., and in the second receiver the fraction obtained between 270 deg. C. and 300 deg. C. It is necessary to use an air-cooled condenser when the naphthalene begins to come over and to gently heat the condenser with a flame to prevent freezing.

The first fraction is then freed from water by means of a pipette and the fractions combined and refracted. The water is again removed as before and the crude naphthalene allowed to solidify. This is weighed as crude naphthalene.

Ten grams of the crude naphthalene is then weighed on a balance and dissolved in 100 to 200 c.c. of naphthalene-free benzol. When solution is complete make the volume up to 250 c.c., with benzol. Pipette off 5 c.c. of this solution and place in a dry 100 c.c. flask containing 0.7 g. of picric acid and allow the picric acid to dissolve.

When solution is complete place the flask in a water bath at 60 deg. C. and pass air over the solution. Precaution must be taken to keep the liquid level in the flask above the water level. When the benzol is entirely evaporated and the odor of benzol is no longer detected, dissolve the residue in the flask in 10 c.c. of alcohol. Make the volume up to 100 c.c. and cool in an ice bath. Filter off 50 c.c. and titrate with N/10 sodium hydroxide, using methyl red as an indicator. Run a blank determination with 0.7 g. of picric acid and subtract the first titration (times 2) from the blank. This gives the difference due to the formation of naphthalene picrate, and when multiplied by 2.56 gives the grams per liter of naphthalene.

Since a theoretical solution of 40 g. per liter was made, the per cent of naphthalene in the crude naphthalene is calculated by dividing the grams per liter found by 40 and multiplying this result by 100.

It is best, however, to determine a factor on the solution used by running a sample of pure naphthalene in conjunction with the test.

The results on the crude naphthalene are then calculated back to the original weight of tar.

Hydro-electric Development in Ceylon

The Public Works Department, Ceylon, has taken up the work of investigating the island's hydro-electric resources, which work was delayed by the war, and it is expected arrangements will proceed rapidly for the early initiation of the proposed electrification of the island's industries and the partial transformation of the transportation systems for steam to electricity, including the extension and development of the use of electricity for domestic purposes in Colombo and other centers of population. Although the standard American frequency of sixty cycles has been prevalently employed in Eastern countries during recent years the adoption of the British standard of fifty cycles is now recommended.

Bituminous Acid-Proof Coatings for Acid-Proofing Concrete Surfaces*

A Condensed Form of the Recommendations of the Bureau of Standards as to the Coating of Concrete Floors, Vats and Tanks Exposed to Acids, Oils and Similar Substances

THREE methods of treatment have been used for the protection of concrete floors, vats and tanks against mineral acids and acid salts, the method selected depending upon the character of surface to be covered, the concentration and temperature of the acid and whether the coating was required to resist abrasion. The materials are bituminous compositions of various kinds.

BITUMINOUS PAINTS

The bituminous paints are used primarily on account of their cheapness and ease of application and give fair service on tanks or other vessels with rather smooth walls, such as is obtained with a plaster or grout coat, and when exposed to mineral acids of low concentration. Two kinds are marketed—those made with an asphalt and those with a coal-tar pitch base, thinned to the desired brushing consistency with suitable solvents. For acids of the lower concentration, the kind of base selected is immaterial. The efficiency of the coating depends upon its thickness and continuity. This can best be obtained by using a thin priming coat to insure a bond with the concrete surface, and when this is thoroughly dry, carefully applying a thicker coat of similar material. It is important that the concrete surface be fairly dry and dust-free. Special care should be taken to touch up all dull, brown, porous and uncoated spots. At least one week should elapse after the application of the last coat before filling the tank with acid.

Satisfactory material has been obtained on the following specification:

Acid-Proof Black. This material shall be composed of a high grade of bitumen thinned with suitable volatile solvents to furnish a smooth, black product which shall dry in twenty-four hours and be unaffected by mineral acids of specified concentration.

It must contain at least 40 per cent of non-volatile, shall not settle, liver or thicken in the container, and shall conform to the following requirements:

(a) When flowed on a piece of clean sheet iron approximately 4 x 6 in. and 0.016 in. thick and allowed to dry for one week at room temperature, the film must withstand bending double quickly over a rod 5 mm. in diameter without cracking or flaking.

(b) A test piece prepared as above and dried for one week at room temperature shall be laid flat and in different places several drops each of sulphuric acid, specific gravity 1.3, nitric acid, specific gravity 1.23, and hydrochloric acid, specific gravity, 1.09, shall be allowed to remain on the surface of the film for six hours. On examination the film shall show only slight dulling and the metal beneath shall show no corrosion.

BITUMINOUS ENAMELS

The bituminous enamels are used where protection for an indefinite period against relatively strong acids is desired and when the cost of the structure justifies the extra expense of application. They can be employed

both on smooth and rough walls and surfaces, and on account of its thickness, continuity of the coating is more easily obtained. They will not resist abrasion at elevated temperatures.

The bituminous enamel consists of two materials—the priming solution and the enamel proper. The priming solution consists usually of a relatively high-melting-point bitumen, of low susceptibility to temperature changes, dissolved in sufficient volatile solvent to give a paint of thin brushing consistency. The enamel proper consists of a bitumen similar to that used in the primer with or without a finely powdered siliceous mineral filler. Some mineral filler is desirable, as it increases the resistance of the enamel to flowing and sagging at elevated temperatures and to abrasion. The enamel is applied hot over the properly dried priming coat.

The following specification should obtain material suitable for tanks exposed to relatively high and wide variation in temperature:

This material shall consist of a bituminous primer and a bituminous enamel which when applied to concrete surfaces will give a coating which will possess good adhesive qualities, will not flow or sag from a vertical surface at the highest prevailing temperature, will not become brittle at 32 deg. F., and will resist mineral acids of specified concentrations for long periods.

Bituminous Enamel. The enamel shall consist of a homogeneous mixture of a bitumen of relatively high melting point and finely powdered siliceous mineral filler. The total amount of mineral filler, as determined from the ash, shall not exceed 40 per cent nor be less than 15 per cent by weight. Within the above limits the satisfactory working qualities of the enamel shall control the quantity of mineral filler to be used. The mineral filler must be resistant to hydrochloric, sulphuric and nitric acids, and must pass a sieve the openings of which are not greater than 0.14 mm. (0.0055 in.). (This corresponds to about 100-mesh sieve.)

Bituminous Primer. The primer shall consist of a like bituminous material, containing no added mineral matter, thinned with a solvent to a satisfactory brushing consistency. It shall dry to a tacky state in thirty minutes and shall not flash below 30 deg. C. by the Abel closed tester. The solvent used shall have a minimum toxic effect upon workmen applying the primer within an enclosed space.

These materials shall conform to the following requirements:

(a) **Workability.** The enamel and primer shall be applied to dry, clean, dust-free concrete slabs in the following manner: The slabs shall be coated with the primer and when this has dried to the tacky state, the enamel shall be mopped on until a coating 3 to 5 mm. ($\frac{1}{8}$ to $\frac{1}{4}$ in.) thick is obtained. The temperature of application shall not exceed 350 deg. F., at which the enamel shall brush and spread out to a fairly smooth coating.

(b) **Brittleness Test.** The brittleness is best determined by testing the material applied to a steel plate. A steel plate 30 cm. x 30 cm. x 1.6 mm. (12 x 12 x $\frac{1}{16}$ in.) shall be primed and coated to a thickness of 3 to

*A report prepared by the Bituminous Materials and Cement Sections of the Bureau of Standards.

5 mm. ($\frac{1}{8}$ to $\frac{1}{4}$ in.) with the enamel, and after cooling for twenty-four hours shall be subjected to the following test: A 750-g. (1.65-lb.) steel ball shall be dropped from a height of 244 cm. (8 ft.) on the coating at a point at least 10 cm. (4 in.) from the edge of the plate. The plate is to be supported in this test by a block or the floor in such a manner that there shall be support beneath the point of impact. In this test none of the coating shall have shattered from the plate nor shall radial cracks develop longer than 4 cm. (1.0 in.) from the center of the point of impact. The coated steel plate shall then be laid coating downward, on a board through which a hole about 8.9 cm. (3.5 in.) in diameter has been cut. The same steel ball shall be dropped from a height of 244 cm. (8 ft.) and shall strike the steel plate over the center of the hole in the board supporting the plate. The coating must not shatter from the plate by this test nor shall cracks develop in the coating further from the center of the point of impact than the boundaries of the hole in the board.

(c) *Acid Test.* The test piece made in the workability test may be used for this test. The coating shall be unaffected except for a slight dulling when exposed in different places to the action of sulphuric acid, specific gravity 1.3 (about 40 per cent), nitric acid, specific gravity 1.22 (about 35 per cent), and hydrochloric acid, specific gravity 1.09 (about 18 per cent), for twenty-four hours.

Covering Power. The materials shall have the following covering power:

Bituminous primer, 1 gal. to cover not less than 100 sq.ft.

Bituminous enamel, 1 lb. to cover not less than 2 sq.ft., $\frac{1}{8}$ to $\frac{1}{4}$ in. thick.

Application. Extreme care should be taken in the application of these materials so as to obtain a continuous coat free from blisters and pinholes, and bonding well to the concrete surface. The concrete surface should be as dry as possible, and free from oil and grease and all loose particles and dust. The latter can be removed by brushing the surface first with a wire brush and then removing the very fine dust with a soft bristle brush. The primer then should be applied and should be worked thoroughly into all hollows and pores. The bond between the concrete surface and the enamel coat depends to a great extent upon the proper application of the primer. Before the application of the enamel, the primed surface should be thoroughly inspected and all brown, dull or uncoated spots should be touched up. When the primer has dried to a slightly tacky state, it is ready for the enamel.

The enamel should be melted and carefully heated until it is sufficiently fluid for brushing, avoiding decomposition and carbonization. The temperature of the material in the kettle should not exceed 375 deg. F. When fluid it should be mopped on quickly, as it sets and hardens very rapidly.

For tanks below ground or those in which the temperature never exceeds 100 deg. F., material with a lower melting point made from a softer bitumen may be used on account of its greater ease of application.

For tanks in which the temperature range does not exceed 30 deg. F., a slightly more brittle material might be used which although shattering under the impact of a 750-g. (1.65-lb.) ball from a height of 244 cm. (8 ft.) withstands its impact from a height of 183 cm. (6 ft.)

BITUMINOUS MASTICS

The bituminous mastics are used almost exclusively for floors on account of the thickness of the layer which must be applied, but they can be used for tanks or vats if proper care is taken in the application. They are easily applied, bond well to concrete surfaces and resist moderate abrasion and fairly strong mineral acids. They are of two kinds, depending upon whether they are applied hot or cold.

Where a thin surfacing for concrete floors is desired, cold mastic is ordinarily used. This consists of two compositions—the priming solution and the body coat or mastic. The primer consists of a hard asphalt dissolved in a volatile solvent to a fairly thin brushing consistency. The mastic consists of the primer into

which sufficient abestos and finely powdered siliceous mineral fillers are ground so as to obtain a very thick pasty fibrous mass. Occasionally, a finishing coat is applied where a color other than black is desired. In that case pigments are added to the last coat of the mastic. The method of application is as follows: The smooth concrete surface is thoroughly dried and cleaned of all grease and dust. The priming coat is then applied, and when it has dried to the tacky state a thin layer (about $\frac{1}{8}$ in.) of the mastic is trowelled on. When this has dried, successive $\frac{1}{8}$ -in. coats of the mastic are applied until the required thickness is obtained.

The hot mastics are somewhat similar to the mixtures used in laying sheet asphalt pavements. However, they contain a little more asphaltic binder, so that when they are heated to the temperature where the asphalt is fluid they can be poured and trowelled into place. They are satisfactory only when applied in layers 1 in. or more in thickness. When mixed and ready for laying they consist of about 15 per cent of asphaltic binder, about 20 per cent of finely powdered siliceous mineral filler, and the remainder properly graded sand or other aggregate, containing no particles larger than those passing $\frac{1}{4}$ -in. sieve. The proper grading of the aggregate so as to get a composition having a maximum density is very important, as upon it the stability and efficiency of the finished floor largely depends. The thoroughness with which the materials are mixed and the care with which they are laid also contribute to the life of the finished surface.

Hot mastics have given very satisfactory service in a wide variety of chemical and dye manufacturing plants, plating, acid tank and storage battery rooms, the pulp rooms of paper mills, and in the leaching tanks of copper and gold refineries.

For convenience in shipping and handling on the job, the asphalt cement and the powdered mineral filler are usually mixed by the manufacturer and cast into blocks weighing from 50 to 75 lb. each, which are marketed as "rock asphalt mastic." For use these blocks are broken up, melted and fluxed with additional asphalt and mixed with the sand or other aggregate. However, the practice of mixing all of the raw materials on the job in suitable mastic machines is becoming more common, as it is more economical, gives a more homogeneous mixture, and danger of overheating and charring of the asphalt is minimized.

Satisfactory materials have been obtained on the following specification:

Bituminous Acid Proof Mastic. The bituminous mastic shall be composed of asphalt cement, clean, sharp grained sand, and fine absorbent siliceous dust. These materials shall be mixed in the proper proportions and shall be applied hot to the concrete surface, which shall be dry and free from dust and shall have been previously coated with a priming or bonding solution which has just reached the tacky state.

Asphalt Cement. The asphalt cement must be of refined asphalt, and shall be homogeneous and free from water.

It shall meet the following requirements:

Melting point (ring and ball), 150 to 180 deg. F.

Penetration at 25 deg. C., 100 g., 5 sec., 15 to 40.

Total bitumen soluble in carbon bi-sulphide, not less than 90 per cent.

Sand. The sand shall be clean, hard grained and moderately sharp, and shall be free from clay, silt and organic matter.

It shall be well graded from coarse to fine, and when tested by means of the laboratory sieves shall meet the following requirements:

	Per Cent
Passing 4-mesh sieve	100
Total passing 20-mesh sieve	50 to 80
Total passing 50-mesh sieve	not more than 30
Passing 100-mesh sieve	not more than 5

Mineral Filler. The mineral filler shall be any finely powdered acid-resistant siliceous material, 85 per cent of which shall pass a 100-mesh screen.

Priming Solution. The priming solution shall consist of an asphaltic base similar to the asphalt cement and shall be thinned to a good brushing consistency with a suitable volatile solvent.

Mixing. The sand or the mixture of the sand and mineral filler and the asphalt cement shall be heated separately to about 300 deg. F. When the asphalt cement is completely fluid, the hot dry aggregate is stirred in and thoroughly mixed until the mass is homogeneous and sufficiently fluid for pouring. The temperature of pouring should be between 350 and 400 deg. F. The aggregate if dry may be stirred in without previous heating, but in that case a longer period of heating and stirring will be required.

Laying. The concrete surface shall be primed and allowed to dry to the tacky state. The hot mixture, prepared as above, shall then be poured, spread on, smoothed out and worked into place with suitable tools. After the surface has begun to set, it shall be sprinkled with hard-grained sand and a little mineral dust and rubbed down until it is smooth. The finished layer should be at least 1 in. thick.

Approximate Formula. The composition varies within narrow limits according to the service required of the material, and when ready for laying should be as follows:

	Per Cent
Asphalt cement	12 to 15
Mineral filler	20 to 25
Sand or other aggregate	60 to 70

Names of manufacturers who can probably furnish materials conforming to the foregoing specifications are given in the following list:

Bituminous Paints:

Barber Asphalt Paving Co., Philadelphia, Pa.

Newly Discovered Australian Pigment Deposits

The discovery of an extensive deposit of ocher and sienna at no great distance from the surface and within thirty miles of Adelaide, South Australia, has attracted much local interest, particularly in view of the abnormally high price of imported paint pigments.

Though regarded primarily as a mining proposition the discovery is important in a manufacturing sense. During the years of war several new paint works were established in Australia, but the promoters were handicapped to some extent by the necessity of importing most of the requisite raw materials. This new find of ocher and sienna, therefore, extends the possibilities of the paint industry and should render it largely independent of overseas supplies of the basic pigments.

Oil Shales and Their Economic Importance*

BY MARTIN J. GAVIN†

THE twentieth century has often been spoken of as the age of petroleum, and from many viewpoints it can justly be considered so. Certainly the petroleum industry is one of enormous importance to this country, industrially, financially and economically. The United States, however, at present producing over 60 per cent of the world's total output of petroleum, is not producing petroleum at a sufficient rate to provide for its own domestic consumption. For several years this country has been importing increasing quantities of crude and partly refined oils from Mexico, and has been drawing heavily on domestic stocks of petroleum. Production in the United States is increasing, but it is not increasing at the same average rate as domestic consumption, nor is it probable that in the future domestic production will increase sufficiently to satisfy the demands of domestic consumption, but on the contrary, in the opinion of those best qualified to know, the peak in the curve of domestic production of crude petroleum will be reached in a comparatively few years, whereas the consumption of petroleum and its products will increase at a continually growing rate. This country, then, must turn, and, as the increasing imports from Mexico indicate, is turning, to other sources than the crude petroleum produced in this country to make up the deficit between domestic production and domestic consumption of petroleum and its products.

INDUSTRIAL PRODUCTS DERIVED FROM PETROLEUM

The chief products of petroleum are motor fuels, kerosene, fuel oils and lubricating oils. Of these, the increasing demand for motor fuels or gasoline is perhaps the greatest, and that of fuel oils probably next greatest. The ever-growing use of the internal combustion motor, especially in automobiles and trucks, accounts for the first, and the increasing use of fuel oil, chiefly for steam-raising purposes, accounts largely for the second. Lubricating oils are, of course, of prime importance, as machinery must be lubricated if it is to operate.

GROWING NEED FOR PETROLEUM PRODUCTS SUBSTITUTES

To help make up the deficit in our supply of petroleum we can expect to draw on the enormous potential petroleum supplies of Mexico at an increasing rate, and by the use of new and improved processes of manufacture a greater percentage of the petroleum products for which there is the greatest demand will undoubtedly be obtained from petroleum. The more efficient utilization of these products, as for example through the development and use of the Diesel engine and the gradual change in the design of our present internal-combustion motors, enabling them to use lower-grade fuels, will perhaps tend to relieve the growing shortage. Hydro-electric power, or electricity otherwise produced, can be expected to take the place, to a certain extent at least, of fuel-oil installations on land. However, all these expedients have their practical limitations, and it is to be expected therefore that in the comparatively near future new sources of products similar to those now

*U. S. Bureau of Mines, reports of investigations. A paper presented by permission of the Director, U. S. Bureau of Mines, before the thirteenth convention of the Utah Academy of Science, April 3, 1920.

†Reinery engineer, Bureau of Mines.

being derived from oil-well petroleum will have to be developed. As a matter of fact, some are already being developed.

SOURCE OF PETROLEUM PRODUCTS SUBSTITUTES

There are possibilities of importance in the development of the production and use of benzol as a motor fuel and other coal-tar products as Diesel engine fuels and as substitutes for other petroleum products. There are also important possibilities in the commercial production of alcohol as a motor fuel. In fact, blends of alcohol, benzol and petroleum distillates are being marketed in the East at the present time as motor fuels and are giving satisfaction in use.

Taking all these considerations into account, however, it is the opinion of many that the oil shales of Utah, Colorado, Wyoming, Nevada and possibly other states are extremely important as new sources of products similar to those now obtained from oil-well petroleum. These states contain enormous deposits of oil shales which by proper treatment yield gas, oil and also, if desired, ammonia, of value as a fertilizer. The oil in many respects is similar to oil-well petroleum and yields products similar to those of petroleum.

Oil shales have been worked in Scotland and France for upward of sixty years. In the former country the industry has been successful from a financial standpoint, especially of late years, although it is passing through a difficult period at present. The industry in France has not been nearly so successful as that in Scotland. The success of the Scotch shale industry has been brought about partly by the development of cheap processes for treating the shales and the oils produced from them, but mostly by local conditions, such as competition only with high-priced petroleum products, low labor costs and the fact that the industry grew up in a densely populated region where a ready market for oil and ammonium products was available.

PRODUCTS OBTAINED FROM OIL-SHALE DISTILLATION

Oil shale contains little or no oil as such, but it contains substances which when the shale is subjected to destructive distillation yield gas, crude oil and nitrogen-containing compounds, notably ammonia, as well as other products in small and probably of unimportant value for the most part. Oil shale as a rule must be mined much as coal is mined, crushed, and heated to a relatively high temperature in closed retorts which may operate continuously or intermittently. These steps are necessary to produce the gas, crude oil and ammonia, the latter in solution in the water obtained along with the oil.

The ammonia water is then distilled and the released ammonia passed into sulphuric acid, producing ammonium sulphate. The crude oil must be refined, much as petroleum is refined, to produce the various commercial products. The refining of shale oil is more complex and in all probability more costly than the equivalent refining of petroleum. Undoubtedly, however, the shale oils can be refined and made to yield many products similar to those produced when petroleum is refined. The oils produced from the oil shales of this country will yield gasoline, burning oils and paraffine wax, all of which when properly treated will be satisfactory commercial products. Whether the more viscous grades of lubricating oils, such as lubricants for internal-combustion motors, can be produced from shale oils is doubtful, but it may be possible. Little is

known in this country as to the refining of shale oils, and this statement can be applied generally to the possibilities and technique of oil-shale operations in the United States.

ECONOMIC REQUIREMENTS FOR THE DEVELOPMENT OF AN OIL-SHALE INDUSTRY

The development of an oil-shale industry to one of considerable importance in this country will require the expenditure of many millions of dollars and take a period of many years. Such development will require much research and technical study, and will require the services of trained executives and experienced technicians. Nevertheless, when economic conditions become favorable, it is reasonable to believe that our oil shales will be of great value as a source of oils similar to those now derived from petroleum. An idea of what large-scale development of the oil-shale industry involves may be gained from the consideration that to produce one barrel of crude oil from shale, on the average at least one ton of a tough rock must be mined, crushed, heated to a relatively high temperature, and finally the residue, amounting to about 75 per cent of the original weight of the raw shale, must be disposed of as valueless. The United States now produces over one million barrels of crude petroleum per day.

Our immense oil-shale deposits practically assure us that, come what may, this country will still have its own sources of petroleum products. We should never have to be wholly dependent on foreign countries in this respect. From another standpoint the shales are also of great economic importance. The oil shales, especially of the Rocky Mountain country, occur in sparsely settled regions. Their development on a large scale means the bringing into these regions of a great number of miners and other laborers, often with their families, who will earn their living in the shale fields and spend their money in the same locality. Millions of dollars must be spent in erecting plants, developing mines and the like, much of which will be spent in the states where the oil shales occur. The shale-oil refineries will require sulphuric acid and other chemicals and supplies, which logically will be produced as near to the shale fields as possible, thus bringing in more capital and labor. Transportation facilities will be extended to meet the requirements of the shale operators, thus benefiting the regions now inadequately supplied in this regard. Prices of petroleum products in the regions contiguous to the shale operations can be expected to be relatively lower than they would be if similar petroleum products had to be shipped in.

CONCLUSION

It should again be emphasized, however, that development of an oil-shale industry to a scale sufficient to be of so much economic importance will require much study, time and money. The oil-shale industry is no business for the man of little experience and small capital. It may be compared with the development of the low-grade copper ores of the West, in that it is a large, low-grade, chemical manufacturing enterprise, requiring capital, time and trained men. The investor in oil-shale operations should know that he will probably have to wait for a long time for a return on his investment and that returns in all probability will be conservative. In spite of this, the day of the oil-shale industry is coming. When, it is difficult to predict, but some day it will undoubtedly be one of great importance.

Mid-Continent Gasoline*

By C. K. FRANCIS†

THE gasoline of the Mid-Continent district, which includes the states of Kansas, Oklahoma, Texas and Louisiana, is a product derived from petroleum and natural gas, having a Baumé gravity between 55 and 72; initial boiling point, 90 to 140 deg. F.; a dry point between 370 and 460 deg. F., and is suitable for use in an automobile engine.

There are three methods for producing this gasoline: (1) Direct distillation of petroleum. (2) Cracking, under pressure, certain petroleum products, such as gas oil. (3) Extraction from natural gas by means of compression, absorption and refrigeration. Contrary to the somewhat general opinion, gasoline identical with some refinery gasoline may be obtained from natural gas by the absorption process.

The ordinary refinery equipment will not permit the recovery from petroleum of that very volatile product identical with compression natural gas gasoline. However, by means of suitable towers, condensing and other apparatus, it is possible to condense the petroleum vapors so as to obtain products identical with those obtained from natural gas.

During 1919 the Mid-Continent field produced over 217,000,000 bbl. of petroleum, from which there was extracted over 50,000,000 bbl. of gasoline, and while exact figures are not available, it would probably be safe to venture the opinion that 12,000,000 bbl. more of gasoline was made by special processes in pressure stills. The quantity of gasoline extracted from natural gas in this district was about 37,000,000 bbl. Then approximately 100,000,000 bbl. of gasoline was obtained last year from petroleum and natural gas out of the Mid-Continent district and placed on the market.

It is the object of this paper to outline and briefly describe some of the tests used for determining the prominent characteristics of gasoline.

The greater proportion of the gasoline marketed is obtained by the distillation of petroleum and consists of the first fraction, or cut, condensed. This product is for convenience called crude benzine.

TREATMENT OF CRUDE BENZINE

The crude benzine is transferred from the receiving tank, commonly known as a run-down tank, to a specially constructed vessel called an agitator. Most agitators in the Mid-Continent field have a capacity of from 1,000 to 2,000 bbl. When these are used singly or in pairs they are known as batch agitators because the charge of the product to be treated is a known quantity. Sometimes agitators are erected and connected in series; usually the system consists of from six to ten tanks through which the liquid passes while being treated, each unit or agitator containing the proper chemical or liquid for treating the crude benzine. Such units are known as continuous agitators. It is now the common practice to mix or agitate the crude benzine and the purifying agents by means of compressed air.

While the charge is being agitated, strong sulphuric acid is added. The quantity of acid used may vary from 1 to 15 lb. per bbl. of product treated according to its condition and the specific results desired. The

next step is to wash the benzine free from acid by showering water through it. Then, in order to be very certain that no acid remains and to remove sulphur compounds, it is washed with dilute caustic soda which is saturated with litharge. Free sulphur is added to aid in the precipitation of the lead sulphur substances. The charge is finally washed with water.

DISTILLING TREATED BENZINE

The treated benzine is pumped to a steam still and redistilled. The vapors from this may be led through special towers which serve to divide them while slightly cooling and the resulting streams may be further separated in the receiving house. In this manner a series of streams are divided from one tank to another and a number of finished gasolines produced.

Cushing, Inola and Bixby crudes (Fig. 1), which are representative of the best crudes of Oklahoma, begin to decompose or crack when approximately 60 per cent of the total volume has been distilled.

Up to this point the products extracted from the crude oil are separated by direct distillation on a basis of their boiling points. Between 550 and 700 deg., chemical decomposition takes place, with the result that the boiling point is materially lowered owing to the

FIG. 1. DISTILLATION CURVE OF BIXBY CRUDE OF 34.6 DEG. GRAVITY

formation of cracked products from the wax or lubricating oil portion of the crude. This illustrates the difficulty of using crude petroleum in the ordinary motor. The decomposition of the oil and resulting deposition of carbon and heavy substances, including coke, brings out clearly the fact that refining is necessary for the production of an ideal motor fuel.

Probably the most apparent property of gasoline to the owner of his first car is that of color, and he with

*Paper read at the May 29, 1920, meeting of the American Chemical Society and Society of Mechanical Engineers, Tulsa, Okla.
†Technical superintendent and chief chemist, Cosden & Co., Tulsa, Okla.

his fellows soon learn to demand, without knowing why, a product which must be as clear as a crystal. Gasoline, being the lightest of the common liquids obtained from the distillation of petroleum or from natural gas, should be free from the heavy oils and asphaltic substances which would produce a yellow to brown color. A very light yellowish tinge may be caused by a dirty tank, contamination with coloring matters contained in packing of the seams of the tank, faulty refining and occasionally as a result of the addition of an inferior or heavy petroleum product. The common cause of the yellowish tint found in many gasolines is faulty refining. A very large part of the gasoline on the market is the product of cracking processes. The cracking process causes the formation of unsaturated compounds and these in turn are the cause of many gasolines going off color. The unsaturated compounds are removed to a great extent by washing the unfinished gasolines with sulphuric acid.

GASOLINE DISTILLATION TEST

All gasolines used for motor fuel are subjected to the distillation test, which includes:

(a) The determination of the temperature at which the gasoline boils, or more accurately when the first

FIG. 2. EFFECT OF BLENDING OF GASOLINE WITH KEROSENE ON THE DRY POINT DISTILLATION

drop falls from the end of the condenser tube; this is known as the initial boiling point.

(b) The rate of distillation, which is determined by observing the temperature for each 10 per cent of the distillation.

(c) The dry point, or the temperature when there is no liquid remaining in the bottom of the flask, commonly known as the end point.

(d) The maximum temperature, or the highest temperature recorded at the end of the distillation.

It is unfortunate that the terms end point and maximum temperature are often confused. The dry point is

probably more often considered to be the end point than the maximum temperature, because the dry point is the temperature registered at the end of the distillation or, specifically, when no liquid remains in the flask and the observation is usually aided by the fact that there is a slight puff of smoke formed when the last particle of liquid is vaporized. The maximum temperature, on the other hand, is the highest temperature recorded during the operation of heating and may be the dry point. The maximum temperature is a point not so easily checked as the dry point and the higher temperature may be due to superheating and not actually be a physical characteristic of the gasoline.

A convenient method for illustrating the results of distillation tests is by means of a temperature per cent curve, the ideal gasoline being one that produces a

distillation curve which may be represented by a straight line inclined upward at an angle of about 30 deg., having a downward turn at the left end and an upward turn at the right end. The beginning of the curve shows the starting quality; the long straight line, the even distribution of the energy; and the upward turn at the end indicates the proportion and character of the heavier liquids present.

The illustration (Fig. 2) includes a number of curves representing blends made with a fair grade of gasoline and good kerosene. These curves show very clearly the influence of both products. The gasoline when present to the extent of only 10 per cent lowers the boiling point to below 200 deg. F., while the kerosene, a heavy liquid, may be easily detected in every mixture and its behavior is well indicated from the starting of the curve through to the end point. While the initial boiling point of a heavy product may be lowered appreciably by the addition of a small quantity of light liquid, it is not possible to decrease the end point or lower the boiling points of the last fractions of a blend. The heavier particles persist and may be detected in a blended gasoline when present in very small quantities.

A comparatively low initial boiling point is a desirable property for a gasoline, because it insures easy starting of the motor. But should there be no rise in the curve the liquid would be too light for motor cars and the quantity required would be large, due to the exceedingly rapid rate of vaporization. A good body or staying quality is derived from the heavier constituents of the gasoline, and is indicated on a distillation curve by the uniform rise after the first 20 per cent fraction has distilled. An exceedingly rapid rise to the curve

would indicate the presence of a large quantity of heavy oils which might cause the deposition of carbon in the cylinders. Just what a safe rise would be and the proper end point have not been determined. The temperature of the explosion chamber is probably over 2,000 deg. F., and if the correct quantity of air were admitted, there can be no question that all ordinary gasolines would be altered to gaseous forms when exposed to so much heat.

SULPHUR IN GASOLINE

The petroleum of the Mid-Continent district seldom contains more than 0.3 per cent sulphur and if the gasoline is properly refined it should contain less than 0.01 per cent total sulphur, but gasoline may be accepted on contract up to 0.04 per cent total sulphur. As indicated above, free sulphur is added to the unrefined gasoline during the refining process and if extreme care is not exercised the sulphur may be added in excess with the result that the completely refined gasoline will contain more sulphur than the untreated or unrefined product. Indeed the examination of a large number of gasolines indicates that many refiners are accidentally adding sulphur to their gasoline in this way. The harmful effect of the sulphur is evidenced in the corrosion of the copper tubing, the brass connections and the cylinders of the motors. The sulphur in the gasoline is particularly injurious to the brass and copper connections, with the result that the feed system often becomes clogged by the black scales collecting upon the openings to the vacuum feed. The sulphur is also deposited in the cylinders, and this, together with other black substances, is commonly called carbon. Analysis of this black deposit shows less than 65 per cent carbon, the remaining 35 per cent being made up of oil, asphalt, iron, silica and sulphur. Under the temperature existing in the cylinders, there can be no doubt that the sulphur combines with the iron and eventually causes serious damage.

DETERMINATION OF SULPHUR IN GASOLINE

A convenient and simple method for detecting the sulphur in gasoline has been proposed. A small piece of polished copper, or a clean penny, is placed in a beaker, covered with gasoline and heated over a steam bath for fifteen minutes. At the end of that time the copper is removed and examined. The surface will be found to have become tarnished or blackened according to the quantity of free sulphur. Analysis indicates that the deleterious action of the free sulphur becomes apparent when it is present to the extent of 0.008 per cent and very bad and corrosive in action when it is present to the extent of 0.018 per cent. The accompanying table gives the physical and chemical properties of Mid-Continent straight run gasoline obtained by direct distillation from the crude petroleum and a sample of unrefined pressure gasoline made by distilling gas oil under pressure.

In a very short period gasoline has advanced from an annoying substance to a product of great commercial importance. When first used as a motor fuel very simple requirements for quality were mentioned; usually gravity, covering a broad range, and color were sufficient.

The gasoline on the market today is classified under very carefully drawn specifications as illustrated in the accompanying table.

The Potash Deposits of Alsace

One of the outstanding questions of the great war was "Will Alsace be restored to France?" This question, full of national interest and appeal as it was to France and Germany, was of still wider commercial interest, for the only known deposits of potash of proved commercial value in the world except the deposits near Stassfurt, Germany, are in Alsace. The search for deposits in the United States, however, is being continued, and in that search a study of the origin, extent, and value of the deposits in Alsace is likely to be very useful. For this reason Hoyt S. Gale, of the United States Geological Survey, and Frank K. Cameron, of the Bureau of Mines, were sent to Alsace early in 1919, soon after the armistice had been signed, to examine and report upon the deposits there.

LOCATION OF THE DEPOSITS

The potash deposits of Alsace lie beneath an open stretch of the valley of the Rhine in southern Upper Alsace, about 25 miles north of the Swiss border.

No evidence of either the potash or of the large masses of common salt that are associated with it is found at the surface; the potash was discovered only by borings put down in search of coal. Under the German rule a large part of the potash field was owned and operated by the great potash monopoly, the German Kali Syndikat. All the potash properties in this region are now in the hands of representatives of the French Government.

THEIR DEPTH AND CHARACTER

The potash deposits lie at depths ranging from 1,200 to 2,200 ft. below the surface, in two beds, one about 60 ft. below the other, which are mined through concrete lined shafts, somewhat as coal is mined. The appearance of the deposits in place is striking. They present high walls of sparkling crystalline salts, banded in nearly horizontal more or less wavy stripes of red and white, resembling a part of an immense flag. Much of the crude material is used for fertilizer after crushing only. In the refining processes the mother liquors are used repeatedly, as the accumulation of impurities in them is slow, this being considered one of the advantages which the French field has over the German. The resultant product from the refining of the Alsatian potash is a high-grade chloride.

QUANTITY OF POTASH IN ALSACE

Before the war, when the world's supply of potash was controlled by the Kali Syndikat, the mines in Alsace produced about 5 per cent of the total world's output of potash, equivalent in 1913 to about 220,000 tons of crude mixed salts containing 41,000 tons of potassium oxide (K_2O), or actual potash. The material mined carries an average of 18 per cent of potassium oxide. The deposits in Alsace are estimated to contain 300,000,000 tons of potassium oxide, enough to supply the world's need at the normal rate of consumption before the war for about 275 years.

Mr. Gale's report on the examination of these deposits has been published by the United States Geological Survey, Department of the Interior, as Bulletin 715-B, under the title "The Potash Deposits of Alsace." The report contains a valuable bibliography and is illustrated by a small map and several half-tone views. It may be obtained without charge from the Director of the Geological Survey at Washington.

Effect of Arsenic in Steel

BY P. E. MCKINNEY*

IN VIEW of the fact that the question has frequently arisen as to the effect of varying percentage of arsenic in steel, it was deemed expedient to make a few experiments in connection with the regular manufacturing operation on the effect of this element.

Two series of experiments were made. The first consisted of a comparison between a plain converter steel and steel from the same heat to which had been added 0.1 per cent arsenic. The second series was identical except that an addition of 0.5 per cent arsenic was made.

After adding the final addition to a regular converter heat, a 3 $\frac{1}{2}$ -in. diameter x 32-in. long split ingot mold was top poured from a bull ladle for the plain test. Then about 3 in. of steel was poured into a hot bull ladle of about 100 lb. capacity to cover the bottom, the metallic arsenic, mixed with several times its weight of thermit and wrapped in paper, was thrown in ladle, the ladle was then filled with steel, mixed and top poured into a similar mold. This constituted the arsenic test ingot; both series were handled in the same manner.

The ingots were stripped the following morning, sent to forge shop, heated and forged longitudinally from bottom end to $\frac{3}{4}$ in. square and cut into 6-in. lengths, a convenient size for test-bars. They were not soaked or annealed before forging, but both series worked excellently while being forged. All of the 6-in. lengths were annealed at 1,400 deg. F. and then heat treated as shown in tabulation of results. The ingots whose heat numbers are followed by the letter A are those to which arsenic was added.

The result of these tests shows practically no difference between the steel containing no arsenic and that to which arsenic has been added, and if anything the result of test shows slight superiority in favor of the steel containing arsenic. While these tests were made on small ingots and the test-piece received considerable longitudinal forging work, the results of these preliminary tests would not indicate that arsenic has

the detrimental effect to steel attributed to it by some authorities.

There is no noticeable difference in the properties of steel containing arsenic as compared with that to which no arsenic additions were made. In the pouring or forging the steel acted normal in every respect.

While it is evident from these experiments that 0.3 per cent arsenic is not injurious, as far as static testing can disclose, the fact must not be lost sight of that it is extremely hard to get rid of arsenic after it is once present in steel and if the steel is used for scrap purposes after its usefulness has ceased, there is a constant automatic augmentation of the arsenic content which will in time get beyond the limits desired. It would also be interesting to note the effect of arsenic upon shock-resisting qualities of the steel, which is of major importance where ordnance work is concerned.

Washington, D. C.

Tests for Defects in Spring Steel

During the progress of some experiments made by the Bureau of Ordnance, U. S. N., to produce suitable recoil springs from a lot of $\frac{3}{4}$ -in. round silicomanganese spring steel numerous breakages were obtained in the 24-hr. solid clamping test of the finished springs. In most cases the breaks showed deep seams. In torsion tests of the same material to determine the properties imparted by various heat treatments seams developed throughout the length of the specimen. In order to guard against receipt of such bars in the future it was first suggested to make a short torsion test of a fixed percentage of each lot. This would be an expensive procedure, and it was therefore decided to determine the effect of compression on a short length of the full size bar. This opened widely the seams noted in the above material and on twenty samples of material now in stock showed only three defective pieces. None of the defects was as serious as those in the $\frac{3}{4}$ -in. silicomanganese steel. A paragraph is therefore being added to the specifications for spring steel requiring compression of a test piece of a length 1.5 times the thickness of the bar to a length equal to the thickness of the bar. This compression is sufficient to clearly indicate serious defects.

Wire-Baking Electric Oven

The application of electric heat to the process used in making steel wire has given such excellent results and is so economical of operation that it should be of interest to operators of all plants where wire drawing is done.

In the manufacture of steel wire the rods as received from the hot rolls are pickled in acid to remove the scale, dipped in lime-water to neutralize the excess acid, and then baked, to drive out the "acid in the steel," the amount of baking depending on how small the wire is to be drawn. If it is to be drawn only one or two holes, a short bake is enough, but for five or six holes the stock must be baked for several hours to withstand the severe drawing. The wire may be, in some cases, additionally heated to dry off grease or oil, or for a low anneal.

At the plant of the Halcomb Steel Co., at Syracuse, N. Y., where the following operation figures were obtained, there are two electric drying ovens, using G.E. apparatus, 16 x 6 x 6 ft. with 96-kw. connected, used for drying off the wire, at a maximum temperature of 600 deg. F., the other 40 x 6 x 6 ft. with 234-kw., for drying "acid in the steel," the wire being in the oven from 1 to 10 hr. at an average temperature of 350 deg. F. Coke and steam heated ovens are also used to do the same work. Thus it is possible to obtain comparative operation costs.

The following data show the cost of operation of the electric and coke oven for a considerable period of time on the ovens used in drying grease and oil from the steel, with normal production, and also the figures applicable if full production had been possible. The work of electric power in these tables is figured at \$0.95 per kw.-hr.:

ELECTRIC			
	— Production —		
	Normal	Max	
Cost of power, net ton steel	\$5.087	\$1.19	
Annual charges per net ton	7.839	727	
Total cost per net ton	\$12.926	\$1.917	
COKE			
Cost coke per net ton	\$0.921	\$0.171	
Annual charges per net ton	21.368	1.983	
Total cost per net ton	\$22.289	\$2.154	

The efficiency of the electrically heated oven as actually operated amounts to 3.73 lb. per kw.-hr., or 535 kw.-hr. per ton, the maximum figures being 16 lb. per kw.-hr., or 125 kw. per ton.

The figures on the operation costs of the kiln for drying "acid in the steel" also show a greater economy in the use of the electric oven.

ELECTRIC			
	— Production —		
	Normal	Max	
Cost power, per net ton steel	\$0.787	\$0.515	
Annual charges per net ton	.648	.187	
Total	\$1.435	\$0.702	
COKE			
Cost coke per net ton steel	\$0.253	\$0.145	
Annual charges per net ton	1.766	.510	
Total	\$2.019	\$0.656	

As operated, the efficiency of the electric oven is 24.1 lb. per kw.-hr., or 83 kw.-hr. per ton, while the maximum production figures would be 36.8 lb. per kw.-hr., or 54.4 kw.-hr. per ton.

The use of an electric oven permits accurate duplication of results of the finished product due to the perfect temperature control, whereby the operating temperature can be quickly changed when desired.

Wedge Optical Pyrometer

Accurate measurement and control of high temperatures are essential to the production of the best results in the metallurgical and many other industries. It will soon be considered as absurd for a workman to attempt to estimate a temperature by the unaided eye as to attempt to measure up his work by the eye alone when rules and gages are available. The demand for a simple, portable instrument for temperature measurement, which can be used without long training or expert technical qualifications, has been met by the Wedge optical pyrometer, a reliable and practical instrument, requiring no accessories of any kind, which cannot get out of order, and may be placed with confidence in the hands of any intelligent workman.

This pyrometer can be used whenever the object to be examined shows a distinct coloration, that is to say, for any temperature above 525 deg. C. The size of the object or its distance makes no difference whatever to the reading.

As shown in the accompanying illustration, the instrument consists of a brass tube, furnished with a small achromatic telescope, so arranged that the objective of the telescope focuses the image of the heated body on a movable prism placed inside the tube. The eye-piece of the telescope then reveals the magnified image on the prism to the observer. There is a suitable shield provided, to prevent exterior light reaching the eye. At one side of the tube is a milled head, actuating a rack-and-pinion which moves the prism through the field of vision. The prism is made of specially prepared dark glass, so arranged that it cuts off the light emitted by a heated body at different temperatures. For example, in looking at a heated bar of iron, as the thicker part of the prism comes gradually into the field of vision, the bar appears gradually darker and darker in color, until at a given point the image entirely disappears; this point gives the actual temperature. On

INTERIOR VIEW OF WIRE-BAKING ELECTRIC OVEN

looking at the scale on the side of the instrument, the pointer will be seen at (say) 1,000 deg. C. A similar operation takes place in every estimation. Naturally a little practice is required to decide the exact moment when the color disappears, and here, of course, the practiced eye of the operator comes into play.

The first readings will probably be within 20 deg. C., afterwards to 10 deg. C. or less. When great accuracy

WEDGE OPTICAL PYROMETER

is required, and the heated body or furnace aperture is small, it is advisable to mount the pyrometer on a stand. The accuracy of the Wedge optical pyrometer has been demonstrated by trial by eminent experts under test conditions. It is introduced on the market by the Rohde Laboratory Supply Co., of New York City.

Non-Corrosive Centrifugal Pump

The Duriron Castings Co., of Dayton, Ohio, has placed on the market an improved Duriron single-stage centrifugal pump. Every part of the pump that comes in contact with the liquid handled is of Duriron, and thus resists virtually all acids, alkalis and salts as well as erosion.

Probably the greatest single source of trouble, certainly the most constant one, in acid pumps has been the limited service possible to obtain from the packing.

Contact of the corrosive handled with the packing made its life short, and frequent repacking of acid pumps has been considered a necessary evil. In this pump the packing cannot be touched by the liquid

DURIION CENTRIFUGAL PUMP

carried, inasmuch as the suction is always under vacuum while the pump operates.

Operators should be instructed, however, to drain the pump when not in service and when the vacuum is lost.

All parts of the pump proper may be reached quickly and easily by loosening the bolts, removing the cover plate, and pulling out shaft and runner, and this without disturbing the suction and discharge connections.

By means of a cage gland the lubricant is forced from the container always and only in the direction of the packing.

The impeller is of such design that in case the discharge connections break and the head be reduced, the impeller will not admit more liquid than the motor will handle, so it automatically prevents damage to motor in direct connected installations. Helical vanes in impeller admit a free flow of liquid, consequently there is the least possible erosive action in operation.

The suction and discharge connections are adjustable, and this pump will accommodate itself to any position or angle that may be necessary or desirable under any conditions of installation.

Where the liquid handled carries solids in suspension or material not suitable for the closed type of impeller, an open type that will handle a large percentage of solids may be used.

All parts of the pump are ground to gage and are therefore interchangeable.

New Truck to Save Space, Time and Man Power

A new industrial truck which, with its own power, elevates the loads to sufficient heights to put material in box cars, stock rooms or trucks, without rehandling, has been developed by the Lakewood Engineering Co.,

Cleveland, Ohio. Because of its ability to perform all the functions of a tiering machine as well as those of a load-carrying storage battery truck, the new machine is called the "Tier-Lift." It serves practically every purpose of a load-carrying industrial truck. This apparatus will, with its own power, elevate a 2-ton load to a height of 76 in., or to any intermediate height.

A 4-wheel steer permits turning in a circle 92 in. in radius. This permits easy turning in narrow aisles, or congested parts of a plant, and gives easy entrance into box cars.

There are three speeds forward and three speeds reverse. The controller handle is conveniently located for operation for travel in either direction. The lifting mechanism is operated by means of a specially designed controller with one speed in either direction. The lifting is done by means of high-efficiency steel worm screws. A separate motor is used to raise the load.

The load platform is carried by a cantilever type support and the load is balanced over the load-carrying wheels. Ball bearings are used throughout and by a special design the friction losses in elevating and lowering the load platform are practically eliminated.

Acid-Proofing and Hardening of Concrete

The chemical division of the U. S. S. Lead Refinery, Inc., is producing a new solution for the hardening and acid-proofing of concrete surfaces. The manufacturing operations are carried on at the company's lead refinery located in East Chicago, Ind. This solution has become a product of intense interest to manufacturers of chemicals, particularly those industries where acids or oils enter into the processes, mainly because the tests made up to the present time and still under way show that ordinary concrete is rendered practically inactive to acid solutions and oils.

The concrete surface at the time of each treatment must be free from dirt, oil or grease, and must be dry

TEST WITH ACETIC ACID

and set at the first instance of application. One part of proofing solution is diluted with two parts of water and applied with a brush. After allowing to stand for twenty-four hours the second coat is put on, consisting of equal parts of proofing solution and water. This is allowed to stand for twenty-four hours and a third coat is applied, consisting of two parts of proofing solution to one part of water. When the concrete is very porous a fourth application of straight proofing solution is recommended.

At the completion of the process the surface is dried and flushed with water.

When the solution is thus brought in contact with the concrete, it precipitates acid-resisting compounds into the pores of the mass, causing the new surface to become an entirely different chemical composition from the original concrete, this effect penetrating to a depth of about $\frac{1}{2}$ in. This new surface chemically formed is hard and flint-like in structure and is not attacked by acid solutions or oils. It is also very hard, being resistant to wear, as when put on concrete floors.

It is now in use on floors subjected to acid slops at the Willard Storage Battery Co. and is being considered by a number of chemical firms for the construction of acid tanks. Should it prove successful in the latter case, the benefit to the chemical engineer over the present method of lining these tanks or silos with acid-proof brick is obvious.

The accompanying illustration shows a comparison between a treated and untreated slab of concrete which has been immersed in a 20 per cent acetic acid solution over a long period of time. A complete series of tests on all of the acids is now under way at the Research Laboratory of the U. S. S. Lead Refinery, Inc.

Roto Piston Pump

A totally different application of eccentric motion, obtained through the use of the "Roto-Piston," has been introduced by the Crescent Pump Co., of Detroit, in commercial vacuum and pressure pumps. Manufacturing high-duty, high-speed pumps, direct-motor driven, it has been sought to make durability the outstanding feature. By its ingenious construction and operation this has been so far accomplished as to justify a guaranteed length of life for each pump.

The vacuum pump will pull within $\frac{1}{2}$ in. of mercury pressure under commercial conditions and down to $\frac{1}{10}$ in. in special use, according to the manufacturer's guarantee. Reversed as a compression pump, it will give 20 lb. to the sq.in.

An inner and an outer casing revolve at the same speed, greatly reducing friction, as all contact are rolling contacts. Flywheel vanes, valves and gears are eliminated. A single sliding vane accomplishes a continuous sealing with an oil film protection, being positively held by centrifugal force. It rotates with the inner and outer casings and at almost the same speed, having a sliding contact area of less than 3 in. on the outer casing.

The accompanying diagram illustrates the motion of the pump. One casing revolving on an eccentric alternately creates and fills a space into which air is drawn. At rapid revolution the action is continuous.

An important feature in the pump's long life is the compensation which is automatically made for wear.

ROTO PISTON PUMP

This wear takes place almost entirely in the bearings, which are standard ball and roller bearings. Because of this automatic compensation adjustment is unnecessary and leakage is easily prevented.

Careful balancing of all rotating parts practically eliminates vibration. The complete pump is compact, light and self-air-cooled, and can be easily moved. Heavy foundations are not required.

Porcelain 'Token Money

The city of Meissen and other towns have ordered porcelain coins for local use, to solve the small-change scarcity and obviate the present unclean and easily tearable paper currency. Germany is said to be about to introduce porcelain small-change coins.

Synopsis of Recent Chemical & Metallurgical Literature

Status of the Aluminum Industry in Germany During and After the War.—Among the industries which were most extensively developed in Germany during the war that of aluminum occupies one of the first places. L. DESCROIS has published in the April, 1920, issue of *Revue de Métallurgie* an article on this subject, of which the following is an abstract:

Up to 1914 the role of aluminum was quite unimportant, but the necessities of war required its extensive use by all the belligerent nations and especially by the Central Powers.

Aluminum alloys were extensively used in aeronautics and automobile construction; the iron industry used great quantities of a ferro-aluminum with 10-20 per cent aluminum and 3 per cent carbon as a deoxidizer; an aluminum alloy was used for the manufacture of fuses and even for small change money (pfennigs). Aluminum metal was used as a copper substitute for electric conductors, in fermentation industries and in nitric acid plants. In Austria aluminum powder entered into the manufacture of explosives.

Germany has no bauxite or cryolite deposits, except small quantities of very poor quality in Hesse near Frankfurt-a-M., and previous to the war 95 per cent of the bauxite treated in Germany was imported from France. The aluminum industry was monopolized by two companies; namely, (1) The Aluminium-Industrie Aktien-Ges. of Neuhausen (Switzerland), with plants at Neuhausen (4,000 hp.) and Chippis (50,000 hp.), both in Switzerland; at Rheinfelden, Germany (5,000 hp.), Lissa, Silesia, and Lend-Gastein (15,000 hp.), in Austria, and (2) Gebrüder Giuliani of Mannheim, with plants at Lissa, Silesia, and Martigny, Switzerland (3,000 hp.).

These two companies controlled the entire production of the three states and during 1913 produced 12,000 tons of aluminum—i. e., 17.6 per cent of the total world production. Of this amount Neuhausen and Chippis produced 8,000 tons and Martigny 700 tons, so that the aluminum production in Germany in 1913 was not over 2,500 tons, although its consumption was about 12,600 tons—i. e., 18.5 per cent of the total world consumption.

With the outbreak of the war the supply of raw material was completely cut off and they had to rely on Switzerland for the needed aluminum, which they were able to obtain in exchange for coal. Thus during the second half of 1914 Germany imported from Switzerland nearly 4,000 tons of aluminum, about 9,000 tons in 1915 and more than 10,000 tons during 1916. This contributed to an extraordinary development of the aluminum industry in Switzerland, where in 1917 the production reached 20,000 tons, of which the greater part went to Germany. But even the increase in import did not meet their needs, and so the Germans started to build their own plants as early as 1915. The first aluminum war plant was put in operation at the end of 1915, using as raw material the timely discovered bauxite in the Carso region along the Adriatic Sea of the then Austrian Empire. From

that region about 50,000 tons of bauxite was mined in 1916, besides the supply of the formerly known bauxite mines in Hesse, near Frankfurt-a-M. The need of aluminum encouraged extensive exploration for bauxite, with the result that rich deposits were discovered in Dalmatia and Hungary. Those of Hungary are especially valuable and it has been estimated that there is in reserve about 10,000,000 tons in the Bihar district alone, besides appreciable quantities in the valleys of Jad and Galbina and near Rey, Sonkolyos and Tizfalu.

The Bihar bauxite analyzes Al_2O_3 , 53-60 per cent; SiO_2 , 1.67 per cent; Fe_2O_3 , 20-35 per cent, TiO_2 , 1.5-3 per cent, and in 1915 as much as 50,000 tons was mined from this newly discovered field. It is also said that there was obtained in 1916 from the Oderberg district about 40,000 tons of bauxite analyzing Al_2O_3 , 54 per cent, SiO_2 , 2.6 per cent, Fe_2O_3 , 26 per cent, TiO_2 , 4 per cent. The Dalmatian and Carso mines, especially those of the islands of Veglia, Loparo and around St. Gregory, were worked with Russian prisoners. In May, 1916, it was stated that the German Norton Co. discovered near Laybach great quantities of very pure bauxite, but it would seem that not much use has been made of it, because the official figures given indicate that only 660 tons was mined in 1916 and 4,000 tons in 1917.

Great efforts have been made to recover aluminum from clay or from a mixture of clay with bauxite or cryolite, but it is certain now that all these efforts failed completely.

The importance of aluminum proved such that by the middle of 1916 the Imperial Finance Department approved the formation of three special aluminum companies; namely, (1) Erftwerk Aktien Gesellschaft, (2) Vereinigte Aluminium Werke Akt. Ges. and (3) Innwerk Bayerische Aluminium Akt. Ges. Up to now three new plants have been installed—namely, at Knappsack, near Cologne, by the first named company, and at Bitterfeld and Niederlausitz, by the Vereinigte Aluminium Werke. All these plants get their power from central stations using lignite as fuel. There are now in course of construction two plants by the Innwerk company to use respectively 50,000 and 75,000 hydro-electric hp. It is stated that when all these plants are in full operation their annual production will be 45,000 tons.

Aluminum is destined to occupy a very important place in industry, due to the great variety of applications to which it may be suited and to the relative abundance of the raw material.

The following table giving the production in thousands of tons for 1913, 1917 and after the war, shows the rapid increase in the aluminum industry in the main producing countries:

Countries	ALUMINUM PRODUCTION, THOUSANDS OF TONS					
	1913		1917		After the War	
	Per Cent	According to Mineral Industry	According to Engineering & Mining Journal	According to R. Troger	Per Cent	
United States....	22.5	32.50	90.7	65	65	33.70
France.....	18.0	26.00	20.0	20	20	10.35
Great Britain....	7.5	10.80	6.0	12	12	6.20
Germany.....	1.0 (?)	1.45	6.0	12	40	20.70
Austro-Hungary (now in Hungary and Jugo-Slavia)	1.0 (?)	1.45	5.0	5	25	13.00
Switzerland.....	12.0	17.35	15.0	20	8	4.15
Canada.....	5.9	8.50	14.3	8	7	3.60
Italy.....	0.8	1.15	7.0	7	16	8.30
Norway.....	1.5	2.15	18.0	16		
Total	69.2	99.90	176.0	153	193	100.00

Mr. DESCROIS passes in review at length the prospects for the after-war German industry, and shows that these prospects are very gloomy, due to the low quality of raw material, the percentages of silica and titanium oxide being detrimental, and to the high cost of power. He analyzes the cost prices, especially those given by Dr. Hans Goldschmidt and Dr. C. Dux, both authorities on the aluminum industry, and concludes with the statement that even on the basis of the German calculations Germany will not be able to compete with the American, French and Swiss producers.

Enamels for Sheet Iron and Steel.—In response to the demand for a general treatise dealing with the technology of the manufacture of vitreous enamels for sheet iron and steel, the Bureau of Standards has issued Technologic Paper 165, by J. B. SHAW. This subject has not been treated adequately in any previous publication.

From the standpoint of mechanical equipment the sheet-iron and steel enameling industry has been probably the most progressive of all ceramic industries in the United States. The presses and machinery used for working the steel and forming the shapes are unsurpassed in ingenuity by those used in any other industry, and are constantly being improved. In this respect the sheet-metal enameling industry of this country has led the world. In the strictly ceramic lines of the industry having to do with the preparation and application of the enamels, progress has been less rapid. Up to a few years ago there was very little work carried on, and this little was seldom reported in print. Recently there has been a decided change in this respect. Representatives of the enameling industry have been joining the ceramic technical societies, have been contributing rather liberally to the journals of these organizations, and have been showing a decided interest in developing the technology of sheet-metal enameling. The leading manufacturers of the country are realizing that the sheet-iron enameling industry has reached the limit of development possible so long as it depends upon formulas rather than upon men with technical training which will enable them to improve and manipulate these formulas to meet varying conditions.

In collecting data for this paper an effort has been made to obtain reliable and authentic information wherever available and to correlate it in such a manner as to shed some light on the problems encountered by enamellers. The treatise is a compilation of data dealing with the subject of enameling from various publications, from the note book of the author, from the files of the Bureau, and from the experience of men engaged in the enameling industry in this country.

Among the subjects dealt with in connection with the properties and preparation of steel for enameling are physical and chemical requirements, sand blasting, treatment preliminary to pickling and methods of pickling. A chapter is devoted to the properties of the raw materials used in compounding enamels. The relations between chemical composition and physical properties of enamels are discussed fully. The procedure used in the preparation, applying and firing enamels is described in detail. The calculation of enamel formulas is fully explained and examples are given. The physical properties of enamels are dealt with in some detail and resistance of enamels to chemical action is fully discussed.

Recent Chemical & Metallurgical Patents

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Sulphur.—Crude sulphur is purified by melting or dissolving in a suitable solvent, such as carbon bisulphide, and filtering through precipitated and ignited alumina or magnesia or mixtures thereof, or through ignited bauxite or magnesite or mixtures thereof. Solutions of sulphur obtained by extracting spent oxide with a solvent may be similarly treated. When exhausted, the filtering material is revived by treating with steam or with a solvent for sulphur and then igniting. (Br. Pat. 140,844—1919. J. J. HODD, London, May 27, 1920.)

Extracting Copper.—Lyes, used for lixiviating cupriferous pyrites, flow from a cock on to waste iron plates in a wicker-work basket, suspended above a tank, whereby a thin film of copper is allowed to deposit on the iron. The copper-coated iron is transferred to a tank containing cupriferous solution or lye to allow the film to increase in thickness. Finally, the copper is removed by means of a flexible blade, washed and dried, when it is ready for use for melting down, for electric refining, or for the manufacture of copper sulphate. The product contains 98 to 99 per cent of copper and a very low proportion, 0.35 per cent, of iron. (Br. Pat. 141,290—1919. H. P. SOULIE-COTTINEAU, Paris, June 9, 1920.)

Electrode Furnaces.—A furnace of known type, for the manufacture of hydraulic lime and slow or quick-setting cements by fusion of the ingredients, is provided with electrodes which dip into a crucible 1 and are adjusted by winches 8. Above the crucible is a cylindro-conical shaft 4 into which the materials are fed from a preheater 10. The hearth of the crucible is made of rammed conducting-material, such as earth, resting on a conducting-plate connected with the conductor bar 3. (Br. Pat. 141,142—1919. M. L. BOILOT and J. DAUDIGNAC, France, June 9, 1920.)

ELECTRODE FURNACE

Purifying Oils.

Finely divided calcined phosphate is added to the oil, which may be stirred and kept at 40 to 50 deg. C. On standing, the mixture separates into layers, which are tapped off. The phosphates may be added in a dry state or suspended in water. A calcined natural phosphate such as apatite is used. Products obtained by calcining a mixture of an artificial phosphate,

such as tricalcium phosphate, with a metallic salt of a volatile acid or other substance contained in crude phosphates, e. g. halogen compounds or carbonates, may also be employed. The phosphate may be used in conjunction with other refining-agents. The calcined phosphate may be treated with acids, alkalis or other reagents. The precipitate obtained in treating the oil may be dried and used as a fertilizer. (Br. Pat. 141,028—1919. K. STIANSEN, Sanderfjord, Norway, June 2, 1920.)

Barium Carbonate.—Finely-divided barium carbonate is obtained by treating witherite or artificial carbonate with a fused salt, such as sodium chloride, which dissolves it. A small quantity of an oxidizing agent, such as sodium nitrate, may be added, or air may be blown through to oxidize iron compounds, and any sediment or scum is removed; or the fused mass may be submitted to a reducing atmosphere in the furnace. The material is then discharged into water, which dissolves the solvent salt, leaving the barium carbonate in a finely-divided state. (Br. Pat. 141,925—1919. H. LANGWELL, Stockton-on-Tees, June 23, 1920.)

Steel.—In making steel from scrap, a small part of the charge is melted in an open-hearth furnace with a carburizing agent whereupon the main part of the charge, preheated to about 800 deg. C., is added. Alternatively, the molten carburized metal may be added to the main charge in a separate furnace. The process may be worked as a continuous one. The preheating may be effected in containers erected over the hearth, or portable and traveling preheaters may be used. Metal and slag may be withdrawn from the furnace by means of a siphon. (Br. Pat. 141,956—1919. G. A. JARVIS, Wellington, Shropshire, June 23, 1920.)

Recovering Volatile Solvents.—In an apparatus for recovering volatile solvents, especially in the rubber industry, in which air is drawn through a closely-fitting hood covering the substance under treatment

and afterwards passed to a condenser, the air within the hood is agitated by a fan or the like, so as to improve its evaporating efficiency. In the arrangement shown, a fan 4 is mounted in the hood 3, which is provided with a counterpoise 6, so that it can be easily raised. The air is withdrawn through a flexible tube 8 provided with a cut-off valve 15 connected to the starting lever of the machine, by which it is closed when the material is not being drawn through the hood. From the hood the air passes to a condenser 10. It may be compressed before passing to the condenser. The condenser tubes may be of circular cross-section provided with hexagonal baffles 16 on a central rod 17, as shown in Fig. 2, to collect entrained liquid. (Br. Pat. 141,210

—1919. D. V. PLUMBRIDGE, South Kilworth, Warwickshire, June 9, 1920.)

Artificial Threads.—To obtain very fine threads from viscose by the drawing-out process, the viscose used is prepared from a "very weak hydrated cellulose," and the original relatively-thick threads are stretched, while undergoing coagulation, in a slowly acting precipitating liquid, such as a 1 per cent sulphuric acid solution. After leaving the coagulating bath the threads are wound on reels revolving in a 2 to 4 per cent solution of sulphuric acid, by which they are finally hardened. (Br. Pat. 141,041—1919. GLANZFADEN AKT.-GES., Petersdorf-in-Riesengebirge, Germany, June 2, 1920.)

Secondary Disazo Dyes.—Secondary disazo dyes are prepared by diazotizing an aminoazo dye of the general formula

(R, R' — aryl radicals, substituted or not), and coupling with an aminonaphthol sulphonic acid, an acetaminonaphthol sulphonic acid, or a pyrazolone containing a carboxyl group or a carboxyl group and a hydroxyl group in its aryl residue. The products are mordant dyes, dyeing wool in acid baths shades which become yellow to red or green-blue when after-chromed, and give similar tints when chrome-printed on cotton. Examples are given of the preparation of dyes from the following parent materials:—4-aminoazobenzene-3:3'-dicarboxylic acid and 1-2'-carboxyphenyl-3-methyl-5-pyrazolone; 4-aminoazobenzene-3:3'-dicarboxylic acid and 1:8:2:4-aminonaphthol disulphonic acid; 4-aminoazobenzene-5'-sulpho-3:3'-dicarboxylic acid and 1-phenyl-5-pyrazolone-3-carboxylic acid; 4-aminoazobenzene-5'-sulpho-3:3'-dicarboxylic acid and 1:8:3:6-acetaminonaphthol disulphonic acid; 4-aminoazobenzene-2:3'-dicarboxylic acid and 1-2'-oxy-3'-carboxy-5'-sulphophenyl-3-methyl-5-pyrazolone; 4-aminoazobenzene-3:4'-dicarboxylic acid and 1-2'-oxy-3'-carboxyl-5'-sulphophenyl-3-methyl-5-pyrazolone. (Br. Pat., 141,401—1919. SOCIETY OF CHEMICAL INDUSTRY, Basel, Switzerland, June 9, 1920.)

Aromatic Amines, Phenols, etc.—Coloration is removed from, or its development prevented in, aromatic amines or phenols or their sulphonic or carboxylic acids by treatment with a small proportion of a hydrosulphite or sulfoxylate, any excess of hydrosulphite or sulfoxylate being finally removed. Thus, a discolored finished product is dissolved or suspended in a solvent, decolorized by adding a small proportion of hydrosulphite or sulfoxylate, and then isolated from the solution or suspension in the usual way; or discoloration may be removed or prevented in a product by adding a small proportion of hydrosulphite or sulfoxylate to the parent materials used in the manufacture thereof. Examples are given of the treatment with sodium hydrosulphite of β -naphthol, benzidine, the solutions of sodium sulphanilate or naphthionate obtained in the manufacture of these acids, or the acidified alkali melts obtained in the manufacture of phenols such as β -naphthol, H-acid, or γ -acid; an example is also given of the addition of sodium hydrosulphite to mixtures of caustic soda solution and sulphonic acids, e.g. aminosulphonic acids, before heating in an autoclave to produce the corresponding phenols. (Br. Pat. 141,440. SOUTH METROPOLITAN GAS CO., London, and H. STANIER, Stoke-on-Trent, June 9, 1920.)

Acid- and Alkali-Proof Aluminum Ware.—Aluminum, aluminum alloys or vessels coated or lined with aluminum are rendered acid- and alkali-resisting by powdering the preliminarily roughened surface with finely-ground carbonate of lime (chalk, mussel shells, etc.), then heating in a furnace to about 550 deg. C. and binding the coating to the aluminum by rolling, pressing, etc. (Br. Pat. 140,069—1919. METALLINDUSTRIE SCHIELE & BRUCHSALER, Hornberg, Baden, May 12, 1920.)

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Purifying Brine.—In the purification of brine for use in electrolytic cells, the calcium sulphate is usually converted into calcium carbonate by means of sodium carbonate. Thus there is formed in the brine an equivalent amount of sodium sulphate, which oxidizes the graphite anode during electrolysis and accumulates in the cell until it interferes with the efficient operation of the latter. For the removal of this sodium sulphate, FRANK G. WHEELER, of Appleton, Wis., has devised an apparatus in which the impure brine is cooled by flowing over pipes containing refrigerated purified brine. The sodium sulphate which crystallizes out adheres to the pipes and has to be removed by a mechanical scraper. The mixture of brine and crystals passes to a settling tank, from the bottom of which the crystals are discharged into a centrifugal drier. The cold purified brine serves to cool the impure brine in a preliminary heat-interchanger. (1,342,519; assigned to Bleach Process Co.; June 8, 1920.)

Acetaldehyde From Acetylene.—In the preparation of acetaldehyde from acetylene, the catalysts used tend to polymerize a part of the aldehyde or to transform it into aldol, crotonic aldehyde, etc. The solution of this problem is the continuous removal of the aldehyde as rapidly as formed. Many methods have been proposed for the accomplishment of this result. The most recent is that of ALFRED GUYOT, of Salindres, France. An apparatus has been devised in which the aldehyde is extracted continuously by the use of a vacuum, which does not, however, act in such a manner as to draw the acetylene gas through the reaction vessel without being fixed. The reaction vessel *A*, into which the acetylene enters through tube *B*, is provided with a powerful agitator *a*. The residual gases escape through *C*. Under the influence of the vacuum pump *G* circulation of the liquid through tubes *D* and *H* is maintained in the direction indicated by the arrows. The rise of liquid in *D* may be assisted by introducing air at *L* or by heating at *K*. Arriving at *F* the acetaldehyde evaporates due to the diminished pressure, and the aldehyde-free liquor returns to the reaction vessel through *H*. Water entering into reaction or lost by evaporation is replaced through *I*. (1,343,715; assigned to Compagnie des Produits Chimiques d'Alais et de la Camargue; June 15, 1920.)

Porcelain.—Porcelain has heretofore been made of a mixture of clay, a flux, such as feldspar, and silica, these ingredients varying somewhat in proportion and chemical purity. The silica has been used as a sort of refractory skeleton or body during the vitrification of the other ingredients. CHRISTIAN DANFÖRSEN, of Schenectady, N. Y., has discovered that the mechanical and insulating properties of porcelain may be improved by using in place of silica, in part or entirely, a stable refractory material, such, for example, as an oxide of zirconium, titanium, aluminum, magnesium, glucinum or thorium. A typical porcelain mixture in a "green" state before firing may consist of 45 parts clay, 35 parts feldspar and 15 parts flint. When a porcelain having the above composition and prepared in the usual manner is heated to 800 deg. C. and then plunged into water it becomes highly fragile so that it can be readily broken apart between the fingers. When the silica in such a composition is replaced by a refractory metallic oxide—for example, zirconia or zircite cement—the finished porcelain can be heated to 800 deg. C. and can be plunged into water without losing its mechanical strength. The modulus of rupture of a sample of porcelain was found to be 4,390; the modulus of rupture of a zirconia porcelain similarly prepared was found to be 7,400. The electrical resistance of ordinary porcelain and zirconia porcelain are closely the same at ordinary temperatures, but at elevated temperatures the electrical resistance of zirconia porcelain is greater than that of ordinary porcelain; for example, at 286 deg. C. the electrical resistance of ordinary porcelain was found to be 0.832 megohms, while at this temperature the resistance of zirconia porcelain is 2.43 megohms. The new porcelains are also less porous than silica porcelain. (1,343,040; assigned to General Electric Co.; June 8, 1920.)

Treating Waste Sulphite Liquor.—A process for the recovery of SO_2 from waste sulphite liquor which leaves the liquor in a favorable condition for fermentation, etc., is described by AUGUST SCHAEFER, of Portland, Ore. The waste liquor as discharged from the blow pit of the digester flows in a thin film over a series of vertically stacked steam-heated coils contained in a chamber in which a vacuum of 5 to 6 in. is maintained by a barometric jet condenser. The heat and diminished pressure facilitate the escape of the SO_2 , which is recovered by absorption in water in a suitable tank situated between the evaporating chamber and the condenser. The remainder of the liquor is discharged through the bottom of the evaporating chamber, neutralized and cooled. It may then be fermented for the production of alcohol. (1,342,721; assigned to Northwest Process Co.; June 8, 1920.)

Halogenation in Side Chain of Aromatic Compounds.—Sulphur chloride (or sulphur) in the presence of acetyl chloride forms an efficient catalyst for the substitution of a halogen in the side chain of an aromatic compound. Thus, in the preparation of benzal chloride, 225 parts of dry toluene is mixed with 4.5 parts of sulphur chloride and 4 parts of acetyl chloride. After heating to 100 deg. C. dry chlorine is introduced rapidly and the temperature raised to 180 deg. C. When the liquid has a specific gravity of 1.272 the flow of chlorine is stopped. The liquid will be found to contain about 245 parts of benzal chloride. The preparation of benzyl chloride and benzotrithloride is also discussed. (1,345,373; LUCAS P. KYRIDES, of New York, assignor to General Chemical Co.; July 6, 1920.)

Current Events

in the Chemical and Metallurgical Industries

Chemical Exposition Greater Than Ever

With accepted applications for space near the 400 mark—a new record—the preliminary details of the Sixth National Exposition of Chemical Industries in Grand Central Palace, New York City, Sept. 20 to 25 inclusive, make certain that the show will outclass the five previous ones. The program, aside from the exhibition proper, is also the most important that has ever been scheduled.

On the afternoon of Thursday, Sept. 23, the Chemical Engineering Symposium will take place. The American Institute of Chemical Engineers will hold a meeting in the Palace in the afternoon, and papers of great interest will be read. In the evening the engineers will have a dinner at the Technology Club.

Three other symposiums will be held during the week. One will be on Fuel Economy, one on Materials Handling, and one on Industrial Management. The Fuel Handling Division and the Materials Handling Division have developed such progress that it is necessary to give each a separate section at the coming Exposition. Important topics will be discussed on the days these two divisions meet.

Entering as it does practically every phase of industry, the Exposition offers a remarkable opportunity to the manufacturer and business man to see what has been accomplished since American chemists entered the field in earnest, or during the war. Discoveries that have revolutionized many manufacturing processes have been made. These have increased production and improved the quality of the merchandise and have resulted in those who have spent money in research finding that the investment paid.

A feature of this year's Exposition will be moving pictures. These will illustrate fields where American chemistry has advanced, and the subjects will be placed before the public in a manner that will enable the lay public to appreciate the difficulties that have been overcome during the past five years.

Research and experiments during the past five years, though successful to a wonderful degree, have proved that despite all that has been accomplished there is still a big field to be explored in dyes, pharmaceuticals and various organic products. American chemists are rapidly solving these problems, but they have no easy task. However, the United States has reached out and grasped the pilot's wheel in world chemistry and its chemists are determined that it will never again relinquish its leadership.

Chemical Merger Reported Consummated

It is reported that the much-rumored combination of the Big Four, the General Chemical Co., The Barrett Co., the National Aniline & Chemical Co. and the Semet-Solvay Co., has actually taken place and that only minor details now remain to be taken care of before the public announcement will be made.

The capitalization of the new company will be about \$200,000,000. It is stated that Barrett Co.'s stock will

be exchanged at the rate of 2.29 new shares for each share of Barrett stock, and that General Chemical Co. will be exchanged on a basis of 3.10 new stock for each share of the present General Chemical Co. stock. The terms under which the Semet-Solvay Co. will be taken in have not been determined, and will depend largely upon the adjustment that is made with reference to the entry of the National Aniline & Chemical Co.

Application will be made to list the new stock on the New York Stock Exchange and it is believed that it will be listed at about \$70 per share and pay dividends at the rate of 6 per cent per annum.

Operation of Government Nitrate Plants Is Urged

Grinnell Jones, chief of the chemical division of the U. S. Tariff Commission, in his recent article published in the *Quarterly Journal of Economics*, summarizes some of his investigations regarding the fixation and uses of nitrogen both in peace and in war. After giving the arguments which have been advanced as to the future policy of the United States with respect to the Muscle Shoals nitrate plant and other plants, this author concludes his article as follows:

A discussion of the pros and cons of private and Government operation of manufacturing enterprises is beyond the scope of this article. The important question is whether the plants are to be operated or dismantled. To allow them to stand idle is nearly equivalent to dismantling them, because they would rapidly deteriorate. Without an experienced operating staff and the constant improvements which come with operating experience they would be of little use in an emergency. If they can earn interest on any figure above their sale price as junk it will be profitable for the Government from a purely financial point of view to have them operated. Moreover, if operated they will be an important military asset and, if the need ever arises, will insure that the United States can make itself independent of imports of nitrate from Chile, just as Germany did. Should this need never arise these plants will continue to furnish a large supply of nitrogenous fertilizers, and thus increase the food supply. There can be no danger of excessive supplies of fertilizer material. There is plenty of land to put it on which has never received a pound of commercial fertilizer. In some way, and soon, the existing legal obstacles to the operation of the plants should be removed in order that they may forthwith contribute to the production of food for a starving world.

Whitehead Made Commissioner of Patents

Vacancies in the offices of Commissioner and First Assistant Commissioner of Patents were filled on Aug. 9 by recess appointments by the President. Robert F. Whitehead is to succeed James T. Newton, who recently resigned as Commissioner of Patents. The new First Assistant Commissioner is Melvin H. Coulston.

Both of the new appointees are lawyers. Mr. Whitehead received his professional training at the University of Virginia and Mr. Coulston at Cornell University. Each has been a member of the Patent Office staff for more than eighteen years. They have occupied positions in the various grades of examiners and are thoroughly familiar with the workings of the office.

Dr. Parsons on the Chemical Industry in Europe

Italy has the foundation of a number of great chemical industries well laid, in the opinion of Dr. Charles L. Parsons, secretary of the American Chemical Society, who just has returned from a three-months' trip in which he looked into chemical matters in several of the European countries. When the lack of raw materials and the scarcity of coal are considered, the Italian chemical development is little short of wonderful, he says. Italy, however, is making effective use of its two great assets, water power and cheap labor. In addition, full advantage is being taken of its supplies of sulphur, salt and the few other raw materials which Italy possesses.

While many chemical lines are being developed, the coal-tar and rubber industries are being conducted on a much larger scale than are any other individual chemical activities. Due to the coal shortage, electrification of the Italian railroads is being extended rapidly, Dr. Parsons reports. He predicts that all the railroads in Switzerland will have been electrified in the very near future.

In Rome Dr. Parsons attended the meeting of the International Union of Pure and Applied Chemistry. He is vice-president for the United States.

The chemical industries of Germany are only staggering along, Dr. Parsons asserts. Coal shortage, transportation difficulties and inability to secure raw materials are obstacles which the German industries are not surmounting with great success. He was particularly impressed with the practical applications which are being made in Germany of liquid oxygen as an explosive. These explosives are being used successfully on small operations, as well as in large mines and extensive works requiring blasting. The Germans have developed machines for the making of liquid oxygen which can be placed on motor trucks and operated by the truck's engine. Machines of this character are made as small as seven liters an hour capacity. He believes that liquid oxygen explosives could be used to great advantage in the United States.

Dr. Parsons made a special study of the application of oxidation of ammonia for the production of nitrous oxides to be used in the chamber process of manufacturing sulphuric acid. Germany is using ammonia almost entirely, he observed. Even in England 30 per cent of the sulphuric acid is being made by the newer process. He satisfied himself that large savings are being made over processes using Chilean saltpeter. He is confidently of the opinion that saltpeter is certain to be displaced in the sulphuric acid industry in this country.

In Scotland Dr. Parsons inspected dye works and paid a visit to the oil shale field.

Decreased American Production of Soda Ash in 1919

The domestic production of sodium carbonate in the form of soda ash was greatly curtailed in 1919. The sales amounted to only 981,354 tons, valued at \$29,824,245, as compared with 1,390,628 tons, valued at \$35,635,520, in 1918, according to R. C. Wells, of the United States Geological Survey, Department of the Interior.

The decreased demand in 1919 was well reflected in the price of soda ash quoted in the New York market. The year began with a sharp decline to \$1.40 a hundred pounds for carload lots, the lowest price quoted for at

least three years, from which there has been a slow and steady rise to the present price of \$3.50 a hundred.

Soda ash is one of the cheapest and most widely used chemicals manufactured. It is used in making glass, soap, paper, caustic soda, chemicals, drugs, paints, leather, enamel ware, and cleansing compounds. Most of it is made from common salt, but a small quantity is obtained directly from the water of Owens Lake, in southeastern California.

The exports of soda ash in 1919 amounted to 50,481 short tons, valued at \$2,656,608. This material was shipped principally to Canada, Brazil, Sweden, Mexico, and Australia, named in order of decrease in quantity exported. The imports amounted to only 415 short tons, valued at \$12,998.

Notes of the Chemical Warfare Service

The Chemical Warfare Service will have about twenty commissions of the lower grades to award this fall. In an effort to arouse interest in obtaining these commissions the heads of twenty-five technical colleges have been apprised of the fact in the hope that some of their students will apply for the places.

The results of the recent examination for commissions are expected by Aug. 20.

With the idea of stimulating outside research on military gases General A. A. Fries plans to request a co-operative agreement with the American Chemical Society. He believes a way can be found to keep the profession interested in the idea of working on gas problems. General Fries points out that it cannot be hoped to secure sufficient appropriations in peace time to conduct the volume of research on military gases which should be in progress. Since all nations are paying considerable attention to chemical warfare, he believes it will be necessary to obtain a considerable amount of outside research if the United States keeps pace with other nations in this regard.

In order that cadets of the United States Military Academy may have a better idea of the uses of gases in warfare the Chemical Warfare Service is staging a series of demonstrations at Lakehurst, N. J., near the cadets' summer camp. Of the new class of cadets twenty-two have applied for transfer to the C. W. S. This is particularly pleasing to General Fries. He points out that while chemists are the most important need of the service, men with military training also are highly essential, since the work of the chemists would be useless unless the gas troops had sufficient military training to allow the orderly use of the chemists' product.

The chlorine plant of the Chemical Warfare Service at Belle, W. Va., has been sold for \$300,000. This is 40 per cent of the original cost of the plant. Since the plant was built under war pressure, almost regardless of cost, the realization is regarded as a very fair one.

Leather Construction in Organs and Player Pianos

Quite an extensive report of the kinds of leather used in the manufacture of certain parts of organs and player pianos has been issued to tanners, dealers and manufacturers. At a conference held in New York on July 20, between the tanners and splitters and a representative of the Bureau of Standards it was decided to experiment with sheepskin skivers in order to produce leather in this country as satisfactory as that now imported.

Growth of the Union Tank Car Co.

During the past two years U.T.L.X. cars have grown from 18,000 to 26,000 in number. The Union Tank Car Co.'s equipment consists entirely of modern all-steel cars of the latest design and built substantially in excess of Master Car Builders' specifications. Entirely aside from its twenty-one shops for the repair of cars, the company's cars alone at present-day valuations very largely exceed the total of its security issues. Such cars cost today in excess of \$3,000, at which figure its 26,000 cars would have a valuation of \$78,000,000.

On the dissolution of the old Standard Oil Co. of New Jersey this subsidiary, formerly known as the Union Tank Line Co., was turned adrift and, incidentally, was compelled to borrow \$1,000,000 immediately required for working capital. By the end of 1917 it had built up a surplus of \$5,463,000 and by the end of 1919 this surplus amounted to \$9,398,000. A record of its net earnings, before deducting depreciation and federal taxes, is as follows:

1919.....	\$6,694,168	1915.....	\$1,606,439
1918.....	6,051,375	1914.....	1,183,568
1917.....	4,467,165	1913.....	1,713,789
1916.....	2,683,145	1912.....	1,815,902

The business of a tank car company consists of owning and keeping in repair tank cars which it leases to the oil-refining companies. Not being a common carrier, it is not subject to the jurisdiction of the Interstate Commerce Commission or of the state commissions and therefore fixes its own charges for the use of cars in ordinary business negotiation with those whom it serves.

Southern Cotton Oil Earnings Over \$2,000,000

The annual statement of the Southern Cotton Oil Co. for the fiscal year ended May 31 shows assets of \$37,256,600 and earnings of \$2,156,688 over dividends, etc.

ASSETS			
Capital assets:			
Real estate, plants and other permanent investments ..		\$12,027,597 82

Co-operation of Bureau of Standards With the American Committee on Electrolysis

Early in the year definite arrangements were made by the Bureau of Standards with the American Committee on Electrolysis, which represents all of the great national associations of utility companies, for co-operative work between that Committee and the Bureau in conducting an extensive research in the field of electrolysis mitigation. After this arrangement had been made, the Committee asked the Bureau to outline a program of research work to be carried out jointly, and such a program was formulated by the Bureau and approved by the Committee. During the last four months a number of somewhat extended investigations have been carried out in co-operation with this Committee in several Middle Western cities. This work has been confined largely, and almost exclusively, to the effect of pipe drainage on underground systems, especial attention being given to the possibility of joint electrolysis on high resistance joints and interchange of current between drained systems. Some attention has also been given to the three-wire systems of power distribution and also to automatic substation installation as a means of electrolysis mitigation. This joint investigation is an extremely important one and it is hoped that means will be found for continuing it during the coming year.

Need of Study on the Changes in the Structure of Hardened Steels Upon Tempering

Work has been started by the Bureau of Standards on quite an elaborate series of examinations to determine the changes which occur in the structure of hardened steels upon tempering. Very little information is available on this subject, and in particular, good micrographs, demonstrating the changes which occur, are rare. It can be shown by such other methods as magnetic tests and density determinations that pronounced changes occur in the hardened steel upon tempering, but the changes in the microstructure are much less plainly marked. For this reason there is need for more careful study of this phase of the metallography of steel. The specimens to be studied will include six different types, varying in carbon content from 0.07 per cent to considerably above 1 per cent. The steel will be hardened by quenching in water from various temperatures, and the length of time at which the material is held at the quenching heat will also be taken into consideration.

Refractories for the Glass Industry

The Bureau of Standards has commenced an investigation having for its object the development of improved refractories out of which to construct pots, etc., for the glass industry, with particular reference to their resistance to corrosion. The principle adopted has been to study systematically such bodies composed of siliceous bond clays mixed with aluminous grog and of aluminous bond with siliceous grog. In this matter it is hoped that the various possible combinations will be covered. A large number of crucibles have already been made from these mixtures. These are being fired, and will then be subjected to the action of a corrosive barium glass. Upon breaking the crucibles, the depth of penetration and degree of attack of the glass upon the material of the crucible will be determined. In addition, the transverse strength of the mixture, both in the dried and in the fired state, as well as the shrinkage, will be measured.

Changes in Exports and Imports of Chemicals

Material increases were shown in both exports and imports of chemicals in June, 1920, as compared with June of last year. This is shown by the latest returns to the Bureau of Foreign and Domestic Commerce. During June, 1920, imports of duty-free chemicals totaled \$12,160,789 and dutiable chemicals totaled \$6,100,996. This compares with \$2,940,273 and \$5,356,904 respectively for June, 1919. The chemicals exported in June, 1920, were valued at \$15,649,608. This compares with \$12,266,274 in June, 1919.

The imports of coal-tar products in June, 1920, totaled \$658,225 in value, as compared with \$341,322 in June, 1919.

The total gums imported in June, 1920, amounted to 14,144,032 lb., valued at \$5,217,950. This compares with imports of 4,605,105 lb., valued at \$1,460,760, in June, 1919.

Acids exported in June, 1920, were valued at \$565,347, as compared with exports valued at \$561,242 in June, 1919. Exports of dyes and dyestuffs totaled \$3,851,180 in June, 1920, as compared with \$1,392,346 in June of last year. Exports of sodas in June, 1920, were valued at \$2,404,080. The exports of June, 1919, were valued at \$1,336,299.

The following tables are intended to show the changes in foreign trading, with records of a few chemicals which move in lesser volume:

IMPORTS OF CHEMICALS

	June, 1919 lb.	June, 1920 lb.
Ammonia, muriate of	157,682	889,999
Arsenic, sulphide of	176,384	351,312
Fusel oil	90,318	662,176
Oil, crude or resublimed	24,717	none
Lime, chloride of	none	33,984
Potash, hydrate of	12,000	197,253
Potash, nitrate of	none	536,645

EXPORTS OF CHEMICALS

Calcium carbide	3,407,436	986,393
Glycerine	429,791	87,420
Lime, acetate of	688,041	262,443
Potash, chlorate	36,989	510,138

Consideration of Others Will Help Coal Shortage

Alarm over the coal shortage, especially in the Western fields, has developed to a point of economic hysteria which is not justified by the facts as investigated through the coal committee of the Chicago Association of Commerce. Harry A. Wheeler, ex-president of the U. S. Chamber of Commerce and chairman of this committee, made an extended report of the findings recently in which he states that the transportation factor is largely responsible for the present shortage and offers the following seven remedies for getting the supply back to a normal basis:

1. Frankly recognize the situation as serious, but one that can be met. Do not get into a hysteria of bidding for coal, thus giving the speculator an opportunity.

2. Comply with every regulation and help the railroads to get the greatest amount of work out of their equipment.

3. Demurrage charges should be graded so that the penalty for retaining possession of equipment for longer than free time will become an expensive and unprofitable operation.

4. Annul the proposition to average the time of cars in possession of the shipper or consignee. This rule invites speculation and carelessness in the use of transportation. The Interstate Commerce Commission and railroads should abandon it during this emergency period.

5. Watchfulness over the rule of the commission which permits the railroads to consign cars to carry coal for their own needs. Railroads must be generous in sharing the equipment with the public.

6. Consumer should take what coal he can get and not wait for products of more distant fields.

7. Conservation. It is estimated that Chicago market may alone save 70,000 cars by March 31. Save coal, save transportation—these are most important.

Mr. Wheeler's analysis shows that common sense and thoughtfulness for the welfare of the other fellow are just as necessary during this reconstruction and readjustment period as it was during the war. Then the majority of men were actuated by unselfish patriotism, now all must work to rebuild business relations. The motive for consideration of general business interests, while not so strong, shows promise of development to a degree far beyond the expectations of the pre-war period.

The Reorganization of Nela Research Laboratories

Nela Research Laboratory was organized in 1908, under the directorship of Dr. Edward P. Hyde, as the Physical Laboratory of the National Electric Lamp Association. The name was changed to Nela Research Laboratory in 1913, when the National Electric Lamp Association became the National Lamp Works of the General Electric Co. For some years the laboratory was devoted exclusively to the development of those sciences on which the art of lighting has its foundation, but in 1914 its functions were extended by the addition of a small section of applied science, which had an immediate practical objective.

The section of applied science is now being largely extended as a separate laboratory of applied science under the immediate direction of M. Luckiesh, who becomes director of applied science, and a new building is being constructed to house this branch of the work, which will be carried forward with a staff of several physicists, an engineer, an architect and a designer, together with the necessary technical and clerical assistants.

Dr. Ernest Fox Nichols, formerly president of Dartmouth College and more recently professor of physics at Yale University, has accepted an invitation to assume the immediate direction of the laboratory of pure science, under the title of director of pure science. The work of this laboratory, which will be continued in the present building, will be somewhat further extended under the new organization.

The laboratory of pure science and laboratory of applied science will together constitute the Nela Research Laboratories, and will be co-ordinated under the general direction of Dr. Hyde, who becomes director of research.

Priority Transportation on Water-Refining Chemicals

Complying with a request of the Public Health Service, the American Railroad Association has issued a circular to all carriers asking that all chemicals used for water purification and the raw materials from which they are to be made be handled as expeditiously as possible. The circular covers the following material when consigned to municipal authorities or intended for the purification of public water supply: aluminum sulphate, bauxite, chlorine, calcium hypochlorite, soda ash, copperas, lime and empty cylinders for chlorine shipment.

The Relation of Composition to the Softening Point of Enamels

A knowledge of the effect of variation of composition of enamels on their softening points is of considerable technical importance in the enameled metal industry. While a few of those relations are understood in a general way, the results of a systematic investigation of the subject have never been published. The Bureau of Standards has undertaken a study of these relations and up to the present time seventy-four enamels, the compositions of which have been systematically varied, have been studied and their softening points determined.

From the data obtained so far it may be stated that the effect of various constituents on the softening point is not in accord with the chemical similarity of these constituents. For instance, certain basic oxides act as refractories in enamels, while others act as fluxes. The same is true for the so-called intermediate oxides and the acid oxides. In a given chemical group of oxides the fluxing effect is not in proportion to the molecular weight, and on the other hand equal percentage amounts of the various oxides do not have the same fluxing effect. The action of each oxide and mineral used in compounding enamels seems to be characteristic of that particular mineral or oxide and cannot be calculated by any system of *a priori* reasoning. It must be determined experimentally.

Hearings on Water-Power Regulations

Sections of the regulations which will be used in connection with the administration of the water-power act are being drafted and made the subject of hearings before officials of the Federal Power Commission. The regulations pertaining to form of application were the subject of criticism and discussion at a hearing on Aug. 12. On the following day representatives of banks and bond houses listened to the reading of the draft of the regulations pertaining to the financial aspects of the law. It is the policy of the commission to submit all regulations to those interested before promulgating them, with the idea of embodying such suggestions and criticisms as may be made.

Those interested in the Great Falls on the Potomac water-power project have been invited to attend a hearing before the Power Commission on Aug. 24. Each of the railroads entering Washington has been asked to send a representative to the hearing. The representatives of all large consumers of power in Washington and in the Great Falls area will be in attendance.

September Meeting of the International Bureau of Weights and Measures

The International Bureau of Weights and Measures will meet in Paris during September of this year. S. W. Stratton, director of the Bureau of Standards, has recently sailed to attend these sessions as the official representative of the United States.

There is in contemplation a considerable increase in the functions of the International Bureau to include other standards than those of simple weights and measures. This idea of extension of activity has been approved by representatives of the American Physical Society, the National Academy of Science and the National Research Council. It is expected that if the plan is adopted the International Bureau of Weights and Measures will have custody of numerous other types of standards and will eventually undertake the study of

physical values and promulgation of constants based upon the best available information. Such constants would doubtless be adopted by most of the interested countries in the form of an international convention with respect to units and standards.

Electrical Smelting Steel Plant Established in Sao Paulo

The establishment in Ribeirao Preto of the Cia. Electrica Metalurgica Brasileira, whose object is the operation of a large electrical smelting plant, marks a new epoch in the industrial development of the State of Sao Paulo. Assistant Trade Commissioner Connell reports that the above-named company, in conjunction with the Empresa Forca Luz de Ribeirao Preto, which is to furnish the power, made final arrangements on May 18 for the erection of the plant at Ribeirao Preto, and work will be started as soon as the American contractors who are to construct the mill can get their engineers on the ground. The capacity of the mill will be sixty tons of steel daily, but it is believed that the plant will turn out only about half that amount during the early months of its operation. The ore is to be mined in the southern part of the State of Minas Geraes and will be hauled seventy-five miles to the mill at Ribeirao Preto, which enjoys easy rail access to the port of Santos, whence ultimate distribution of the finished product will be made. It is interesting to note that the inauguration of this company in Brazil marks the beginning in South America of the use of electricity for smelting purposes.

Ceramic Day at the Chemical Exposition

The committee on co-operation of the American Ceramic Society, H. Schmidt, chairman, is planning to have a Ceramic Day at the Exposition of Chemical Industries Friday, Sept. 24. The custom of having a special day set aside for the members of the Society during which papers are presented is a welcome one, as is indicated by the considerable attendance during the Exposition in Chicago last fall.

Personal

MELVIN H. COULSTON has been appointed First Assistant Commissioner of Patents. Mr. Coulston has been a member of the Patent Office staff for more than eighteen years.

C. O. DICKEN, head of the chemical laboratory of the E. J. Brock & Sons Candy Co., delivered a talk before the Chicago Chemists' Club recently on "Chocolate Refining for Candy."

Dr. GUSTAV EGLOFF of Chicago has been in New York for several days.

Dr. RALPH H. MCKEE recently left for Europe, where he has been called in consultation.

W. T. SCHALLER, after an extended period in private employ, has returned to the position of mineralogical chemist with the United States Geological Survey which he formerly occupied.

GEORGE SLOCUM, who for the past five years has been with the United States Rubber Co., in Java and Sumatra rubber plantation work, spoke before the Chemists' Club at Chicago recently on "Java and Its Rubber Plantations."

GEORGE OTIS SMITH now has the distinction of having served longer as the director of the U. S. Geological Survey than any of his predecessors. He will have completed his fourteenth consecutive year as head of the bureau next

May. The opinion is very generally held that the long tenure of office on the part of the directors of the Survey has been an important factor in the bureau's effectiveness. Clarence King, the first director of the Survey, accepted the position forty years ago only to organize the bureau and served but one year. The remaining thirty-nine years have been divided practically equally among J. W. Powell, C. D. Walcott and Dr. Smith.

F. H. TUCKER has resigned as associate chemist of the Bureau of Standards to take a research position in the New York Laboratories of the Chile Exploration Co. Mr. Tucker has already begun work in his new position.

R. G. WALTENBERG, who for a number of years has been a physicist on the staff at the Bureau of Standards, has been appointed an industrial fellow of the International Nickel Co. to continue research work at the Bureau of Standards on properties of nickel and monel metal. This is one of a number of fellowships recently established at the bureau for co-operative investigation in special industrial lines.

ROBERT F. WHITEHEAD has been appointed Commissioner of Patents, succeeding James T. Newton, who resigned recently.

Dr. L. F. WHITMER, who has been an associate chemist at the Bureau of Standards for a number of years, has recently accepted appointment as associate professor in the department of chemistry of Lafayette College, Easton, Pa. He will have charge of metallurgy and certain inorganic courses in this department from the beginning of the next college year.

Book Reviews

PRACTICAL CHEMISTRY. By N. H. Black and James B. Conant. 474 pp. 251 illustrations. New York: MacMillan Co.

The number of elementary introductory books on chemistry is very large and growing still larger, just as is the subject itself. The authors of "Practical Chemistry" are to be congratulated in having written a book that will give the beginner not only a grasp of the fundamental facts of the science but also some notion of the part played by chemistry in industrial life. The illustrations are excellent and should make it easy for the student to get quick and lasting impressions. While the text has been primarily prepared for class work, there is no doubt that it is suitable for general reading. Copies of it should be in every plant library so that all employees who desire a good start in chemical reading will have it available.

WALLACE SAVAGE.

Current Market Reports

The Iron and Steel Market

Pittsburgh, August 13, 1920.

For a month in which the steel market was reported as dull as it was last month the July unfilled tonnage statement of the Steel Corporation was very favorable, as the unfilled obligations increased by 139,651 tons during the month, this being 100,000 tons more than the 38,351-ton increase of June, and as shipments probably increased 50,000 or 100,000 tons from June to July the bookings appear to have increased by 150,000 or 200,000 tons. Yet July was one of the two proverbially dull midsummer months and June, being the end month of a quarter, should have witnessed the booking of a considerable tonnage of routine business which is simply entered up quarter by quarter.

It is understood that the Steel Corporation subsidiaries have not been soliciting any business, but are simply accept-

ing such part of the business offered them as is to their liking. On account of the disparity in quoted prices by the Steel Corporation and the independents the corporation must hold its facilities for its regular trade. As to the independents, it is said that they are not soliciting business either. Some of them are sold up only a short distance ahead, but to solicit business would be to provoke a question as to why the quotations remain above those of the Steel Corporation, if additional orders are desired.

As an offset to the 11,118,468 tons of unfilled obligations which the Steel Corporation reports at the end of July there is the considerable tonnage that has been produced but not shipped, but this amounts to only about a month's output. At 90 per cent of rated capacity, 52,600 tons per working day, the output in nine months would be approximately equal to the unfilled obligations reported, so that it may be taken that the corporation is booked up approximately to April 1, 1921, as an average date.

STEEL PRODUCTION OFF

The rate of steel ingot output declined about 6 per cent from June to July, the July rate being about 39,900,000 gross tons per annum. The computation is based upon the monthly report of the American Iron and Steel Institute, showing the output of thirty companies which made 84.03 per cent of the total output of 1918, these companies reporting 2,980,690 tons for June and 2,802,818 tons for July. The rate of production of pig iron by steel works furnaces decreased about 2.2 per cent from June to July, the rate of steel ingot production decreasing about 6 per cent, as noted above. However, there is the disturbing element that Independence Day was a steel-mill holiday but not a blast-furnace holiday, and such facts are taken into account in the computations used for this report of production rates. The result is that while the thirty companies produced 178,000 tons less of steel ingots in the month of July than in the month of June the steel interests in general produced about 20,000 tons more pig iron in the latter month. Accordingly it would appear that they accumulated some pig iron, this being quite natural seeing that they accumulated large tonnages of semi-finished steel, production of finished steel being restricted by car shortage and large stocks already accumulated. The circumstance is interesting in view of the fact that merchant pig iron is scarce and furnacemen show a disposition to advance their prices.

In the past few days the Carnegie Steel Co., after a long interval, has been in the market for heavy melting steel scrap and has bought a total variously estimated at 20,000 or 30,000 tons, some of the purchases being at \$29, when ten days ago the market was quotable at barely over \$27 to consumers. It is normal, however, for the buyer of a large tonnage to pay more than the quoted price, for the dealers are buying odd lots every day and selling large lots only occasionally. Usually scrap purchases by the Carnegie Steel Co. are taken as indicating that the steel market has a particularly favorable prospect, but in this case the purchases may have been occasioned by the company having left so much of its steel lately in semi-finished form, whereby the production of works scrap has been temporarily curtailed.

PIG IRON ADVANCING

For several months there has been a waiting attitude in the pig iron market, the question being whether buyers or sellers would act first. The scarcity of prompt iron has caused some buyers to seek iron at whatever price has to be paid and the furnaces are showing a strong disposition to advance prices. Basic recently sold at \$46.50, valley, in important transactions, an advance over the previously quoted market of 50c. Bessemer remains quotable at \$47, valley, and foundry at \$46, valley, but some furnaces are holding out for much higher prices and it is a question whether additional purchases of any of the three grades could be made at the prices here named. Whether an advance in the market predicated upon an insistent demand for early deliveries can be molded into a general buying movement for extended deliveries remains to be seen, but at the moment it looks as if the furnaces had the upper hand. An advancing pig iron market is somewhat anomalous.

lous, seeing that steel prices show more likelihood of declining, by the independents dropping to the Steel Corporation level, yet pig iron prices are already too high in relation to steel prices.

TRANSPORTATION

If anything there is more complaint in the trade regarding transportation conditions than a week or two ago, yet there is no doubt that on the whole shipments of pig iron and steel products have been increasing for a fortnight, if not for a longer period. The shippers had hoped that transportation conditions would be entirely righted by this time, which accounts for their dissatisfaction now. Shipments of pig iron are probably equal to production, but steel still seems to be accumulating, though at a low rate.

Steel interests in the Pittsburgh, valley and Cleveland districts have discovered that a large number of gondola cars owned by railroads endeavoring to serve them are beyond the Mississippi River and are making representations to the Interstate Commerce Commission looking to the issuance of an order that these cars be returned to owner roads, just as box cars owned by Western roads were ordered west some time ago in order to move grain. Car supplies in the Connellsville coke region have been distinctly better last week, and this owing to cars moving somewhat less slowly. It is remarkable that placements have been as good as they have been, in view of the very slow movement. Various furnace interests have related their experience of having to have en route more than double as much coke as normally in order that daily receipts may be up to requirements, which of course means that the cars involved are moving at less than half normal speed.

Lake Superior iron ore shipments down the lakes in July amounted to 9,638,606 tons, a trifle more than in July, 1919, and a trifle less than in July, 1918, which held the record for a July. The season total to Aug. 1 is 26,079,111 tons. Taking the three preceding years as a criterion, using the rate of pig iron production shown each July as the basis of requirements to the opening of navigation the following year, the shipments this year to Aug. 1 fall 3.8 per cent of the indicated tonnage, but that is practically nothing in view of the millions of tons of ore regularly carried at furnaces and on Lake Erie docks. Shipments from Lake Erie docks have been a trifle below their normal relations to the vessel movement.

Several purchases of sheet bars, for conversion into sheets, have just been made at \$70. At least four mills sold at this price, and two or three others would recognize the price. A trifle over a fortnight ago sheet bars brought \$75, also for conversion.

The Chemical and Allied Industrial Markets

New York, August 13, 1920.

The slight activity exhibited in the chemical market during the last week has been confined almost entirely to actual requirements. Spot supplies on some of the items are increasing and as a result there has been an easing up of the firm tone that has been noticeable for some time previously; *formaldehyde* is among the foremost and spot sales are being made as low as 48c. per lb., with the possibility of still further drop due to the improved *alcohol* situation. However, former quotation of \$5.50 per gal. for the *ethyl* grade still holds. Despite the increased cost of production manufacturers are finding it impossible to raise their prices with resale material being offered below the present market. This is the case in *sulphuric acid*, 60 deg., which can be obtained as low as \$12 per ton, and as a result producers are awaiting the fall buying, which it is hoped will be very heavy. The increased arrivals of *barium chloride* from abroad have held this item down and it can be obtained in fairly large quantities at \$150 per ton, although there is not enough material on hand yet to meet the normal demand. Due to weak inquiry both *caustic soda* and *potash* fell off during the week and the former is now quoted at 27@28c. per lb., while the latter is being held at \$6@\$6.50 per cwt. in resale lots.

COAL-TAR PRODUCTS

There is very little to report in this market during the week, as business has been very dull. The closing of a number of textile plants has cut off the only source of demand that has kept this market moving and a return to normal activity is not looked for before the fall. Some idea of the rise in *naphthalene* can be gained from the following table:

	Crushed	Flake	Balls
May, 1919.....	\$0.06-\$0.08	\$0.07-\$0.08	\$0.10-\$0.11
March, 1920.....	.06—.08	.07—.08	.10—.11
April, 1920.....	.08—.09	.07—.08	.08—.10
May, 1920.....	.15	.15	.15
June, 1920.....	.15	.15.17	.16—.18
July, 1920.....19	.19
August, 1920.....18—.20	.19—.21

The sudden rise in April was caused by a combination of circumstances; first, scarcity of the crude material, second, the dropping out of the market of one of the largest producers when a fire partly dismantled the plant. Although it is nominally quoted at 19@21c. today in small resale lots, deliveries on contracts, written in the early part of the year, are still being made at 6@8c. crushed, 7@8c. flake and 8½@10½c. per lb. for balls.

NAVAL STORES AND FLOTATION OILS

Heavy buying inquiry from England and South America is putting this market back on the road to normal prices. Advances have been made in all grades of *rosin*, and although there is very little material available in the local market Savannah has been active during the week, especially in the last few days. *Turpentine* has been quiet during the week, with very few inquiries, the former quotation of \$1.70 still holding firm, with Savannah quoting \$1.56 per gal. The *flotation oils* are somewhat weaker than last week, *pine oil*, steam dist., sp.gr. 0.930-0.940, being listed at \$3.15, against \$2.30 per gal. of previous report. *Crude turpentine*, sp.gr. 0.900-0.970, is down to \$1.75 from \$2 per gal.

VEGETABLE OILS

Conditions remain unchanged with low prices still prevailing and a tendency to still lower levels is noticeable. *Soya bean oil*, tank cars, f.o.b. Pacific Coast, sold as low as 9½c. per lb. for spot material, with very few buyers available. Practically the same condition exists in *peanut oil*, concessions being made on spot material and nobody willing to take these offerings. All grades of *coconut oil* are down, *Ceylon* being listed at 17½@18c., against 18½@19c. of last week, while *Cochin* grade fell from 16@16½c. to 15@16c. per lb.

The Baltimore Market

Baltimore, Md., August 12, 1920.

Since last report, the outstanding feature in the fertilizer business has been the heavy export demand and final consummation of order for about 25,000 tons acid phosphate, which has had a tendency to materially strengthen the market.

During the past week the car supply has been somewhat better, and the fertilizer manufacturers are now bending every effort toward getting off their shipments of complete fertilizer for the fall season, but there is still a shortage of labor which is handicapping the trade in general in this section.

Prime cottonseed meal for September-December shipment has further eased off, and is now obtainable as low as \$7.75 per unit of ammonia, delivered Baltimore, no charge for phosphoric acid, potash or bags. Of course this price is based on the present rates of freight, and the increase which will become effective this month is to be for buyers' account. The manufacturers, however, feel that after increased rates go into effect, which will be correspondingly reflected in the delivered price per unit of ammonia, sellers of cottonseed meal will still further reduce their f.o.b. quotations, and are therefore holding off in their purchases awaiting further developments.

ACID PHOSPHATE

Practically all the important sellers of this material are now sold up, and the large export order has about:

cleaned up all the summer surplus. It is reported that 25,000 tons was sold for shipment abroad at \$19 per ton, in bulk, basis 16 per cent delivered to vessel at producer's works, Baltimore, for goods testing 16 to 18 per cent, pro rata charge for excess over 16 per cent. August-September shipments are practically unobtainable, and October-December is nominally quoted at \$19@20 per ton, in bulk, basis 16 per cent, pro rata charge for excess. The lower figure is for shipment by water, while the outside price is for car shipments, with sellers hesitating to take on any important business on account of the car situation, and such orders as are booked for shipment in this manner are subject to car supply permitting. Both phosphate rock and sulphuric acid are in short supply, with only occasional offerings on the market, which are eagerly taken up at market prices. Every indication points not only to the market being maintained, but ruling higher later on when it will be more a question of securing the goods than of price.

TANKAGE

While there has been an easing up in the Western market, which is now nominally \$7.50 and 10c., f.o.b. Chicago, this price with freight added figures considerably higher than buyers have to pay Eastern packers, and foreign ammoniates are again coming into favor, as these are obtainable on a lower basis than packing house byproducts. Foreign nitrogenous material testing about 8 to 9 per cent ammonia and guaranteed 80 per cent availability is obtainable at \$7.50 per unit, delivered Baltimore, but as only a limited tonnage of this class of material is required by the fertilizer manufacturers for their fall mixtures, more interest is shown in later deliveries than for August-September arrivals.

NITRATE OF SODA

There has been a further recession in the market on this article, due to the lower rate of sterling exchange. August-September deliveries are now obtainable at \$3.65@ \$3.70, October-December \$3.80@ \$3.90, and January-April \$3.95@ \$4.

It is understood that the easiness of the market is attributed to the foreign exchange situation, and if there should be an upward turn, there will doubtless be a corresponding increase in nitrate, as this material is being firmly controlled at producing point.

POTASH

There have been no new developments in this since last report, as the fertilizer manufacturers are all holding off in their purchases in anticipation of their being able to secure their supplies for the coming spring season at materially lower prices than now prevail. In the meantime, only meager supplies of foreign potash are being received, and these are being quoted at somewhat lower than the previous market.

Early deliveries of muriate are now obtainable at \$2.40@ \$2.50, kainit at \$2@ \$2.10, and manure salt at \$2.10@ \$2.20.

FISH SCRAP

The market remains stationary at \$7.50 and 10c. for dry unground scrap, f.o.b. factories, subject to catch and if made. However, on account of financial conditions the buying demand has eased up, but producers are comfortably fixed by having contracts which were booked some time ago.

BONE MEAL

While the market on 3 and 50 per cent steamed bone meal remains at \$54 per ton in buyers' bags, and little interest being shown at this price, every indication points to still higher prices ruling on this article, as well as raw bone meal, when the increased freight rates go into effect. The tonnage available is very limited, and while the present high prices have curtailed consumption, the material is not being produced in a large way, and any lots quoted under the market are rapidly absorbed.

Calcium carbide.....	lb.	.04 - .04 1/2	.04 - .05 1/2
Calcium chloride, fused, lump.....	ton	25.00 - 30.00	35.00 - 45.00
Calcium chloride, granulated.....	lb.	.01 1/2 - .01 1/2	.02 - .03 1/2
Calcium hypochlorite (bleaching powder).....	cwt.		4.50 - 6.00
Calcium peroxide.....	lb.		1.50 - 1.70
Calcium phosphate, monobasic.....	lb.		.75 - .80
Calcium sulphate, pure.....	lb.		.25 - .30
Carbon bisulphide.....	lb.	.08 - .09	.10 - .11
Carbon tetrachloride, drums.....	lb.	.14 - .15	.16 - .17
Carbonyl chloride (phosgene).....	lb.		.80 - 1.05
Caustic potash (see potassium hydroxide).....			
Caustic soda (see sodium hydroxide).....			
Chlorine, gas, liquid-cylinders (100 lb.).....	lb.	.09 - .09 1/2	.10 - .10 1/2
Chloroform.....	lb.	.10 - .13	.14 - .17
Cobalt oxide.....	lb.		2.00 - 2.05
Copper (see iron sulphate).....			
Copper carbonate, green precipitate.....	lb.	.27 - .28	.29 - .31
Copper cyanide.....	lb.		.60 - .70
Copper sulphate, crystals.....	lb.	.08 - .09	.09 - .09 1/2
Cream of Tartar (see potassium bitartrate).....			
Creosote (see creosote sulphate).....			
Ethyl Acetate Com. 85.....	gal	1.13 - 1.13	1.40 - 1.75
Ethyl Acetate pure (acetic ether 98% to 100%).....	gal		1.75 - 2.00
Formaldehyde, 40 per cent (nominal).....	lb.	.40 - .45	.55 - .60
Furfural, red.....	gal		5.25 - 6.00
Furfural, crude (nominal).....	gal		
Glyceric acid (see sodium sulphate).....			
Glycerine, C. P. drums extra.....	lb.	4.30 - 4.35	4.40 - 4.45
Glycerine, resublimed.....	lb.		.40 - .45
Iron oxide, red.....	lb.		2.20 - 2.50
Iron sulphate (copperas).....	cwt.		13 - 16
Lead acetate, normal.....	lb.		.15 - .17
Lead arsenate (paste).....	lb.	.11 - .12	.13 - .14
Lead nitrate, crystals.....	lb.	.14 - .15	.15 - .16
Litharge.....	lb.		1.50 - 1.55
Lithium carbonate.....	lb.	.12 - .13	.15 - .16
Magnesium carbonate, technical.....	100 lb.	3.50 - 3.90	4.00 - 4.50
Magnesium sulphate, commercial.....	100 lb.		3.5 - 4.0
Nickel salt, double.....	lb.		.14 - .16
Nickel salt, single.....	lb.		.13 - .14
Phosgene (see carbonyl chloride).....			
Phosphorus, red.....	lb.	.50 - .55	.60 - .65
Phosphorus, yellow.....	lb.		.35 - .37
Potassium bichromate.....	lb.	.50 - .55	.57 - .60

	Carlots	Less Carlots
Potassium bitartrate (cream of Tartar) . . . lb.	\$0.52 - \$0.56	\$0.57 - \$0.58
Potassium bromide, granular . . . lb.		.70 - .73
Potassium carbonate, U. S. P. . . lb.	.50 - .55	.56 - .60
Potassium carbonate, crude . . . lb.	.20 - .25	.26 - .28
Potassium chlorate, crystals . . . lb.	.16 - .17½	.18 - .20
Potassium hydroxide (caustic potash) . . . lb.	.27 - .28	.29 - .33
Potassium iodide . . . lb.		3.35 - 3.60
Potassium nitrate . . . lb.	.17 - .17½	.19 - .21
Potassium permanganate . . . lb.	.75 - .80	.85 - .95
Potassium persulfate, red . . . lb.	.90 - 1.00	1.05 - 1.10
Potassium persulfate, yellow . . . lb.	.32 - .36	.35 - .40
Potassium sulphate (powdered) . . . ton	\$225.00 - 240.00	
Rochelle salts (see sodium potas. tartrate)		
Salammoniac (see ammonium chloride)		
Salt soda (see sodium carbonate)		
Salt cake . . . ton		40.00 - 50.00
Silver cyanide (nominal) . . . oz.		1.25 - 1.60
Silver nitrate (nominal) . . . oz.		1.25 - 1.60
Soda ash, light . . . 100 lb.		3.20 - 3.50
Soda ash, dense . . . 100 lb.		3.25 - 3.65
Sodium acetate . . . lb.	.10 - .15	.20 - .25
Sodium bicarbonate . . . 100 lb.	2.50 - 2.75	3.00 - 3.50
Sodium bichromate . . . lb.	.22 - .24	.26 - .27
Sodium bisulphate (nitre cake) . . . ton	7.00 - 8.00	9.00 - 11.00
Sodium bisulphate Powdered, U.S.P. . . lb.	.08 - .10	.10 - .11
Sodium borate (borax) . . . lb.	.09 - .10	.11 - .12
Sodium carbonate (sal soda) . . . 100 lb.	1.50 - 1.80	1.80 - 2.00
Sodium chlorate . . . lb.	.11 - .12	.12 - .14
Sodium cyanide, 96-98 per cent. . . lb.	.25 - .30	.32 - .35
Sodium fluoride . . . lb.	.18 - .20	.20 - .22
Sodium hydroxide (caustic soda) . . . 100 lb.		6.25 - 7.00
Sodium hyposulphite . . . lb.		.03 - .04
Sodium molybdate . . . lb.	2.50 - 3.00	3.25 - 4.00
Sodium nitrate . . . 100 lb.	3.00 - 3.25	3.75 - 4.00
Sodium nitrite . . . lb.	.16 - .18	.19 - .20
Sodium peroxide, powdered . . . lb.	.32 - .35	.35 - .40
Sodium phosphate, dihydrate . . . lb.	.03½ - .04½	.04 - .05
Sodium potassium tartrate (Rochelle salts) lb.		.39 - .40
Sodium prussiate, yellow . . . lb.	.23 - .27	.31 - .32
Sodium silicate, solution (40 deg.) . . . lb.	.01½ - .01¾	.02 - .02½
Sodium silicate, solution (60 deg.) . . . lb.	.02½ - .03	.04 - .05
Sodium sulphate, crystals (Glauber's salt) cwt.	1.60 - 1.70	1.75 - 2.50
Sodium sulphate, crystals, 60-62 per cent (conch.) lb.	.09 - .10	.10 - .11
Sodium sulphate, crystals . . . lb.	.04 - 0.4½	.04 - .05
Strontium nitrate, powdered . . . lb.	.15 - .18½	.19 - .20
Sulphur chloride red . . . lb.	.08 - .09	.10 - .10½
Sulphur, crude . . . ton	16.00 - 20.00	
Sulphur dioxide, liquid, cylinders . . . lb.	.09 - .10	.10 - .12
Sulphur (sublimed), flour . . . 100 lb.		3.80 - 4.35
Sulphur, roll (brimstone) . . . 100 lb.		3.40 - 3.90
Tin bichloride (stannous) . . . lb.	.42½ - .44	.45 - .46
Tin oxide . . . lb.		.55 - .65
Zinc carbonate, precipitate . . . lb.	.16 - .18½	.19 - .20
Zinc chloride, gran. . . lb.	.13 - .13½	.14 - .17
Zinc cyanide . . . lb.	.45 - .49	.50 - .60
Zinc dust . . . lb.	.11 - .12	.12 - .13
Zinc oxide, U. S. P. . . lb.	.17 - .25	
Zinc sulphate . . . lb.	.03½ - .03¾	.04 - .06

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude . . . lb.	\$1.40 - \$1.50
Alpha naphthol, refined . . . lb.	1.60 - 1.70
Alpha naphthylamine . . . lb.	.51 - .55
Argline oil, drums extra . . . lb.	.33 - .34
Aniline salts . . . lb.	.40 - .42
Anthracene, 80% in drums (100 lb.) . . . lb.	.90 - 1.00
Benzaldehyde (f.o.b.) . . . lb.	2.00 - 2.10
Benzidine, base . . . lb.	1.35 - 1.40
Benzidine, sulphate . . . lb.	1.15 - 1.25
Benzoic acid, U. S. P. . . lb.	.90 - 1.00
Benzonitrile of soda, U. S. P. . . lb.	.80 - .90
Benzol, pure, water-white, in drums (100 lb.) . . . gal.	.35 - .40½
Benzol, 90% in drums (100 lb.) . . . gal.	.33 - .38½
Benzyl chloride, 95-97%, refined . . . lb.	.35 - .40
Benzyl chloride, tech. . . lb.	.25 - .35
Beta naphthol benzoate (nominal) . . . lb.	3.50 - 4.00
Beta naphthol, sublimed (nominal) . . . lb.	
Beta naphthol, tech (nominal) . . . lb.	.85 - .95
Beta naphthylamine, sublimed . . . lb.	2.25 - 2.40
Cresol, U. S. P., in drums (100 lb.) . . . lb.	.18 - .19
Ortho-cresol, in drums (100 lb.) . . . lb.	.23 - .25
Cresylic acid, 97-99%, straw color, in drums . . . gal.	1.05 - 1.15
Cresylic acid, 95-97%, dark, in drums . . . gal.	1.00 - 1.05
Cresylic acid, 50% first quality, drums . . . gal.	.65 - .75
Dichlorobenzol . . . lb.	.08 - .10
Diethylaniline . . . lb.	1.50 - 1.60
Dimethylaniline . . . lb.	1.35 - 1.45
Dinitrobenzol . . . lb.	.30 - .37
Dinitrochlorobenzol . . . lb.	.32 - .35
Dinitronaphthalene . . . lb.	.45 - .55
Dinitrophenol . . . lb.	.40 - .45
Dinitrotoluenol . . . lb.	.35 - .40
Dip oil, 25%, tar acids, car lots, in drums . . . gal.	.38 - .40
Diphenylamine (nominal) . . . lb.	.80 - .85
H-acid (nominal) . . . lb.	2.00 - 2.25
Metaphenylenediamine . . . lb.	1.25 - 1.50
Monochlorobenzol . . . lb.	.18 - .20
Monothylaniline . . . lb.	2.00 - 2.40
Naphthalene crushed, in bbls. (250 lb.) . . . lb.	
Naphthalene, flake . . . lb.	.19 - .19
Naphthalene, balls . . . lb.	.19 - .19
Naphthionic acid, crude . . . lb.	.75 - .85
Nitrobenzol . . . lb.	.14 - .19
Nitro-naphthalene . . . lb.	.40 - .50
Nitro-toluenol . . . lb.	.18 - .25
Ortho-amidophenol . . . lb.	3.25 - 4.25
Ortho-dichlor-benzol . . . lb.	.15 - .20
Ortho-nitro-phenol . . . lb.	.80 - 1.25
Ortho-nitro-toluenol . . . lb.	.25 - .40
Ortho-toluidine . . . lb.	.35 - .40
Para-amidophenol, base . . . lb.	2.50 - 3.00
Para-amidophenol, HCl . . . lb.	2.50 - 3.00
Para-dichlor-benzol . . . lb.	.08 - .12
Paranitraniline . . . lb.	1.35 - 1.40

Para-nitro-toluenol . . . lb.	1.35 - 1.50
Paraphenylenediamine . . . lb.	2.50 - 2.65
Paratoluidine . . . lb.	2.00 - 2.25
Phthalic anhydride . . . lb.	.60 - .70
Phenol, U. S. P., drums (dest.), (240 lb.) . . . lb.	1.12 - 1.20
Pyridin . . . gal.	2.00 - 3.50
Resorcin, technical . . . lb.	4.25 - 4.50
Resorcin, pure . . . lb.	6.25 - 6.75
Salicylic acid, tech., in bbls. (110 lb.) . . . lb.	.50 - .52
Salicylic acid, U. S. P. . . lb.	.50 - .60
Salol . . . lb.	.90 - 1.00
Solvent naphtha, water-white, in drums, 100 gal. . . gal.	.33½ - .35½
Solvent naphtha, crude, heavy, in drums, 100 gal. . . gal.	.25 - .26
Sulphanilic acid, crude . . . lb.	.32 - .35
Toluidine . . . lb.	1.70 - 2.50
Toluidine, mixed . . . lb.	.45 - .55
Toluol, in tank cars . . . gal.	.35 - .40½
Toluol, in drums . . . gal.	.38½ - .40½
Xylidine, drums, 100 gal. . . lb.	.50 - .65
Xylo, pure, in drums . . . gal.	.47½ - .50½
Xylo, pure, in tank cars . . . gal.	.45 - .50
Xylo, commercial, in drums, 100 gal. . . gal.	.32½ - .35½
Xylo, commercial, in tank cars . . . gal.	.30 - .35

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark . . . lb.	\$0.36 - \$0.39
Beeswax, refined, light . . . lb.	.37 - .38
Beeswax, white pure . . . lb.	.63 - .68
Carnauba, No. 1, (nominal) . . . lb.	.90 - .95
Carnauba, No. 2, regular (nominal) . . . lb.	.55 - .60
Carnauba, No. 3, North Country . . . lb.	.35 - .36
Japan . . . lb.	.17 - .18
Montan, crude . . . lb.	.35 - .36
Paraffine waxes, crude match wax (white) 105-110 m.p. . . lb.	.09 - .09½
Paraffine waxes, crude, scale 124-126 m.p. . . lb.	.09½ - .10
Paraffine waxes, refined, 118-120 m.p. . . lb.	.11 - .12
Paraffine waxes, refined, 125 m.p. . . lb.	.12 - .12
Paraffine waxes, refined, 128-130 m.p. . . lb.	.14 - .15½
Paraffine waxes, refined, 133-135 m.p. . . lb.	.16 - .17
Paraffine waxes, refined, 135-137 m.p. . . lb.	.17 - .18½
Stearic acid, single pressed . . . lb.	.24 - .25
Stearic acid, double pressed . . . lb.	.25 - .26
Stearic acid, triple pressed . . . lb.	.27 - .28

NOTE—Paraffine waxes vary seasonally.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940 . . . gal.	\$2.15
Pine oil, pure, dist. . . gal.	1.80
Pine tar oil, ref., sp. gr. 1.025-1.035 . . . gal.	.48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla. . . gal.	.35
Pine tar oil, double ref., sp. gr. 0.965-0.990 . . . gal.	.85
Pine tar, ref., thin, sp. gr. 1.080-1.060 . . . gal.	.36
Turpentine, crude, sp. gr. 0.900-0.970 . . . gal.	1.75
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990 . . . gal.	.35
Pine wood creosote, ref. . . gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-I, bbl . . . 280 lb.	\$14.00 - \$16.25
Rosin E-I . . . 280 lb.	16.00 - 16.75
Rosin K-N . . . 280 lb.	17.00 - 17.20
Rosin W-G-W-W . . . 280 lb.	17.25 - 17.50
Wood rosin, bbl . . . 280 lb.	15.00 - 15.50
Spirits of turpentine . . . gal.	1.70 - 1.75
Wood turpentine, steam dist. . . gal.	
Wood turpentine, dest. dist. . . gal.	
Pine tar pitch, bbl . . . 200 lb.	8.50 - 8.50
Tar, kiln burned, bbl. (500 lb.) . . . bbl.	14.50 - 15.00
Retort tar, bbl. . . 500 lb.	15.00 - 15.50
Rosin oil, first run . . . gal.	.72 - .75
Rosin oil, second run . . . gal.	.75 - .78
Rosin oil, third run . . . gal.	.92 - .95

Solvents

75-76 deg., steel bbls. (85 lb.) . . . gal.	\$0.40
70-72 deg., steel bbls. (85 lb.) . . . gal.	.38
68-70 deg., steel bbls. (85 lb.) . . . gal.	.37
V. M. and P. naphtha, steel bbls. (85 lb.) . . . gal.	.29

Crude Rubber

Para—Upriver fine . . . lb.	\$0.33 - \$0.34
Upriver coarse . . . lb.	.21½ - .22
Upriver caucho ball . . . lb.	.21 - .21½
Plantation—First latex crepe . . . lb.	.30 - .30
Ribbed smoked sheets . . . lb.	.29½ - .29½
Brown crepe, thin, clean . . . lb.	.27 - .27
Amber crepe No. 1 . . . lb.	.29 - .29

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls . . . lb.	\$0.16½ - \$0.18
Castor oil, AA, in bbls . . . lb.	.19 - .19
China wood oil, in bbls . . . lb.	.15 - .18
Cocanut oil, Caylon grade, in bbls . . . lb.	.15 - .16
Cocanut oil, Cochon grade, in bbls (nominal) . . . lb.	.16½ - .16½
Cora oil, crude, in bbls . . . lb.	.14 - .15½
Cottonseed oil, crude (f.o.b. mill) . . . lb.	.10 - .11
Cottonseed oil, summer yellow . . . lb.	.12 - .13
Cottonseed oil, winter yellow . . . lb.	.17 - .18½
Linseed oil, raw, car lots (domestic) . . . gal.	1.50 - 1.50
Linseed oil, raw, tank cars (domestic) . . . gal.	1.40 - 1.40
Linseed oil, boiled, car lots (domestic) . . . gal.	1.56 - 1.56

Olive oil, commercial.....	gal.	3.00	—	3.10
Palm, Lagos.....	lb.	.10	—	.10
Palm, bright red.....	lb.	.10	—	.10
Palm, Niger.....	lb.	.11	—	.12
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.12	—	.12
Peanut oil, refined, in bbls.....	lb.	.17	—	.18
Rapeseed oil, refined in bbls.....	gal.	1.40	—	1.50
Rapeseed oil, blown, in bbls.....	gal.	1.60	—	1.70
Soya bean oil (Manchurian), in bbls, N. Y.....	lb.	.14	—	.14
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.09	—	.11

FISH

Winter pressed Menhaden.....	gal.	\$0.90	—	\$1.05
Yellow bleached Menhaden.....	gal.	0.95	—	1.05
White bleached Menhaden.....	gal.	1.00	—	1.25
Blown Menhaden.....	gal.	1.00	—	1.20

Miscellaneous Materials

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Colorado

DENVER—The Tungsten Products Co. is building a chemical reduction plant for the exclusive treatment of radium ores in connection with its plant at Boulder. Estimated cost, \$7,000.

Illinois

CHICAGO—The Charles H. Miles Bldg. Co., 2443 West 21st Pl., plans to build a 1-story, 100x200-ft. plant at West 35th and South Leavitt Sts. Estimated cost, \$150,000.

MONTICELLO—The Bd. of Educ. has awarded the contract for the construction of a 2-story, 111x172 ft. school, to Alfred Nelson, 36 West 18th St., Chicago, at \$200,000. A chemical laboratory will be installed in same. Noted June 23.

Iowa

CENTERVILLE—The Judy Mfg. Co. has awarded the contract for the construction of a 1-story, 60x150-ft. foundry, to the B. S. Staley Constr. Co., at \$30,000.

Kentucky

LOUISVILLE—The Louisville Chemical Co., 108 South 3rd St., is in the market for machinery for its new factory. R. F. Gregory, pres.

Maryland

ANNAPOLIS—The Public Utilities Co. plans to construct gas-plant additions. Estimated cost, \$200,000.

Massachusetts

BOSTON—The Boston & Maine R.R. Co., North Station, will soon award contract for the construction of an overhead sewage disposal system, at Warren Bridge.

EAST EVERETT (Boston P. O.)—The Carpenter-Morton Co., 77 Sudbury St., Boston, has awarded the contract for the construction of a 4-story, 50x60-ft. factory on East Summer St., to J. B. Locatelli & Co., Inc., 46 Cornhill St., Boston. Estimated cost, \$75,000.

SOMERSET—N. S. Chase, engr., Borden Block, Fall River, will soon award contract for the construction of a 1-story, 70x160-ft. iron foundry. Estimated cost, \$50,000. Owner's name withheld.

Michigan

DETROIT—The National Alloys Co., Woodbridge St., plans to build a 1-story, 60x100-ft. foundry. Estimated cost, \$25,000. Horace H. Lane, Dine Bank Bldg., engr.

Minnesota

PINE ISLAND—The Bd. of Educ. plans to build a 2-story, 60x106-ft. high school. L. L. Cornwell, secy., Stebbins & Haxby, 415 Auditorium Bldg., Minneapolis, archts.

Montana

FORSYTH—John E. Edwards & Co. plans to build a sugar factory. Estimated cost, \$1,500,000.

Nebraska

MINATARE—The Great Western Sugar Co., Scotts Bluff, plans to build a sugar factory with a capacity of 1,200 tons.

New Hampshire

DOVER—The National Woodworking Machinery Co., B'way., has awarded the contract for the construction of a 1-story 50x100-ft. foundry, 1-story 35x200-ft. machine shop and a 1-story 40x100-ft. pattern shop on Locust St., to Chesley & Co., 11 Middle St. Estimated cost, \$125,000.

New Jersey

ATLANTIC CITY—The city is having plans prepared for the construction of a sewage disposal plant. Estimated cost, \$60,000. Clyde Potts, 30 Church St., New York City, engr.

Ohio

CANTON—The Bowman Bros. Drug Co., 3rd and Court Sts., N. W., has awarded the contract for the construction of a 2-story warehouse on Schroyer Ave., S. W., to the Van Orman Bros. Estimated cost, \$60,000.

CINCINNATI—Hill Griffith, 1262 State Ave., plans to build 1- and 1-story, 150x300-ft. addition to foundry. Estimated cost, \$100,000. Bert Baldwin, 2nd National Bank, engr.

CLEVELAND—The Cleveland Can Co., 1836 Euclid Ave., plans to build a 3-story factory. Estimated cost, \$200,000. J. A. Brown, 1836 Euclid Ave., mgr.

PIQUA—The Champion Bldg. Co. has awarded the contract for the construction of a 2-story factory to the Dorris Hunt Constr. Co., Dayton. Estimated cost, \$15,000.

URBANA—The United Paper Board Co. is having plans prepared for rebuilding and remodeling its plant recently destroyed by fire. Estimated cost, \$500,000.

Pennsylvania

PHILADELPHIA—The Taylor Wharton Iron & Steel Co., 25th and Washington Sts., has awarded the contract for the construction of a 1-story, 80x100-ft. machine shop addition at 51st and Grays Sts., to the Hughes-Foulkrod Co., Commonwealth Trust Bldg.

Rhode Island

CUMBERLAND—A. H. Humes, archt., 229 Main St., Pawtucket, will soon award the contract for the construction of a 1-story, 60x80-ft. factory on Abbott St., for the Standard Nut & Bolt Co. Estimated cost, \$25,000.

PAWTUCKET—The Whist Cheer Chemical Co., Grotto Ave., will build a 1-story addition to its factory. Estimated cost, \$35,000. Work will be done by day labor.

Texas

AMARILLO—The city plans to vote on a bond issue for the construction of an incinerator, \$18,000; sanitary disposal plant, \$18,000; sanitary sewers, \$60,000; fire alarm station, \$30,000; and a coliseum, \$200,000. Address the Mayor.

Wisconsin

CUMBERLAND—The city will build a sanitary sewer system and treatment plant. Estimated cost, \$80,000. Work will be done by day labor. Noted July 7.

GRAND RAPIDS—The Grand Rapids Bldg. Co. will build a 1-story, 50x104-ft. pattern shop here. Work will be done by day labor.

MENASHA—The Simple Gas Engine Wks. plans to build a 60x100-ft. foundry. J. D. Frankland, De Pere St., mgr.

WAUKESHA—The Waukesha Castings Co., 340 B'way., is in the market for new foundry equipment. W. Blair, purch. agt.

WEST ATLIS—The Nelson Pulley Co., 857 27th St., Milwaukee, will build a 1-story, 60x120-ft. machine shop and foundry. Work will be done by day labor.

Ontario

HAMILTON—The Steel Wks. of Canada, Harvey Lane, plans to build a 1- and 2-story steel plant and foundry. Estimated cost, \$300,000.

KAPUKASING—The Spruce Falls Co., Toronto, plans to build a pulp and paper mill here. Estimated cost, \$800,000.

ST. THOMAS—The Elgin Milk Products Co. plans to build a 2-story, 55x200-ft. condensed milk factory on Talbot St. Estimated cost, \$100,000.

ST. THOMAS—S. Gilbert, mgr., will soon award the contract for rebuilding the plant, which was recently destroyed by fire, of the Canada Iron Bldg. here.

Manufacturers' Catalogs

THE WELLMAN-SNAVER-MORGAN Co., Cleveland, O., calls attention to Bull. 51, on its new gas producer. This bulletin is practically a text-book on gas producers, and has also many illustrations, some in color.

PORTABLE MACHINERY Co., Passaic, N. J., has just published a 24-page catalog entitled "Portable Conveyors." This is complete with illustrations showing the various uses of the Scoop Conveyor and other portable conveyors manufactured by the company, and describes clearly the labor, time and money saving features of the machines in storing, reclaiming, loading and unloading material such as coal, coke, ashes, sand, gravel, crushed stone, fertilizer, cement, chemical, etc. Copies of the catalog will be sent free upon request to the manufacturers.

THE NATIONAL CARBON Co., Inc., New York, has issued a booklet entitled "The Carbon Electrode." The purpose of this booklet is to place in the hands of those interested in electric furnace operation certain suggestions relative to the handling, storage and use of carbon electrodes, and a comprehensive bibliography.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its 1920 meeting Dec. 27, 1920, to Jan. 1, 1921, at Chicago, Illinois.

AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Chicago, Sept. 7 to 10 inclusive.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in the Hotel Statler, Cleveland, Ohio, Sept. 30, Oct. 1 and 2.

AMERICAN FOUNDRYMEN'S ASSOCIATION will meet in Columbus, Ohio, Oct. 4 to 8 inclusive.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its one hundred and twenty-second meeting Aug. 20 to Sept. 3, on Lake Superior.

AMERICAN MINING CONGRESS will hold its next convention in Denver Nov. 15.

AMERICAN PAST SOCIETY will hold its annual meeting at Madison, Wis., Sept. 2, 3 and 4, 1920.

AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

AMERICAN STEEL TREATERS' SOCIETY, Chicago, will hold its second annual convention and exhibit, combined with the convention of the Steel Treating Research Society of Detroit, Mich., in the Coliseum Museum, Philadelphia, Pa., Sept. 14 to 18 inclusive.

ASSOCIATION OF IRON AND STEEL ELECTRICAL ENGINEERS will hold its 14th annual convention at the Hotel Pennsylvania, New York City, Sept. 20 to 24, 1920.

ENGINEERING COUNCIL will hold its next meeting in Chicago Thursday, Oct. 21, 1920.

INSTITUTE OF METALS DIVISION OF THE A.I.M.E. will hold its usual joint meeting with the American Foundrymen's Association at Columbus, Ohio, during the week beginning Oct. 4.

IRON AND STEEL INSTITUTE (British) will hold its autumn meeting at Cardiff by invitation of the Ironmasters and Steel Manufacturers of South Wales and Monmouthshire. The date of the meeting will be Tuesday, Sept. 21, for the assembling of the members at Cardiff, and the formal proceedings will open on the morning of Wednesday, Sept. 22.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SIXTH) will be held in the Grand Central Palace, New York City, Sept. 20 to 25.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall national convention at Carnegie Music Hall, Pittsburgh, Pa., Nov. 10, 11 and 12, 1920.

TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its fall meeting at Saratoga Springs, N. Y., Sept. 1, 2 and 3.

Fall Conventions And Expositions

AS SUMMER approaches its end, and usually while the dog days are still upon us, we have to roll up our sleeves and get ready for the tumultuous month of September. It becomes a time for pleasant meeting and profitable discourse among men of science and technology. Many regard it as in agreeable post-vacation to attend the meetings. As editors we enjoy them also, but they can scarcely be construed as vacations. Editorial flowery beds of ease seem to be out of commission during September. Indeed, this year from the middle of August to the middle of October there is a continuous succession of professional gatherings in which chemists and metallurgists are interested. Outstanding features are the pilgrimage of the mining and metallurgical engineers to the Lake Superior country, the gathering of chemists in Chicago, the convention and exhibits of the steel treaters in Philadelphia, the Sixth National Exposition of Chemical Industries in New York, the meeting of electrochemists in Cleveland and of the Institute of Metals Division of the A.I.M.E. in Columbus. The dates of these gatherings are given elsewhere in our regular column devoted to that purpose.

Following our usual custom, we will herald the approach of the Chemical Exposition with a special issue, to be published Sept. 8. Literally speaking, months have been spent in its planning and preparation. Leaders in a score of industries have contributed their ideas of the progress which must be made in order to establish those industries on a truly scientific basis. As a consequence the issue will possess special character as a symposium by forward-looking specialists each of whom is in the front rank of his industry. At our invitation they have spoken freely and frankly of those things which must be done if rule of thumb is to be superseded by science. Rarely have we commented in advance upon the quality of material which we expect to publish, but in this instance the product of many minds is not only worthy of advance notice, but undoubtedly will be considered fit for preservation.

Small, but Quite Important

SCARCELY a week passes without announcement of some new fellowship or research award from endowment funds or other agencies interested in the reports of research. However, a large majority of these awards are for sums of \$500 to \$1,000 per year, or less. Recently there was noted one case where six awards were made from a single fund, the largest being \$500, the total less than \$2,000.

It is rather strange that so much attention is given to these small sums, each of which amounts to less

than the annual wage for a new office boy; but they suffice to hold post-graduate students for a year or two of research, or they provide some instructor or professor with enough funds to defray expenses of special apparatus and equipment.

The technical significance of these awards is very great, and they should be encouraged. Indeed, it is high time that our industries took a greater interest in encouragement of special research by the appointment of men at educational institutions or public laboratories that are particularly well fitted to work on their problems. Even though the companies do not realize handsomely on some of these investments, it is more than likely that the benefit from such support of special investigations will far exceed the average success in hiring the afore-mentioned office boy. Certainly there is no more promising way than this to use a small investment for research.

Contentment, Complaint And Present Progress

THE notion remains that a great many things are wrong industrially, financially and economically. It might be well to stop a moment and question whether there is not something wrong with the mirror of the mind that reflects the things observed. Perhaps we are taking things too seriously. It is quite true that progress is made through discontent. If one is contented with his condition he is not likely to strive to get somewhere else. Discontent with things over which one can have no influence, however, is a totally different matter.

The disposition to complain is obviously very strong. That is in part a product of the war and of the war-ending. During the war we saw certain things done by team work, by the people having a common purpose and we feel somehow that in these days everything ought to be righted by similar methods, but that is impossible because the single common purpose that existed during the war is lacking.

It certainly does seem as though discontent and the disposition to complain are greater than they should be or need be. For instance, there is "the transportation situation," which common talk would have it is almost indescribably bad. Transportation conditions have been improving rather steadily since the latter part of April. More freight cars were loaded in July than in June, and more than in July of last year. The quantity of transportation is not up to the requirements, and the quality is not what is desired, for when the freight does move it does not move as rapidly as it should. This is not the first time these things have occurred, but we are particularly sensitive on the subject now on account of the vast amount of public discussion of railroad matters.

Then there is coal. Many people talk as if there were a tremendous shortage, yet the fact is that production is very heavy and is probably in excess of current requirements, apart from the matter of stocking, which of course is desirable. The main thing about coal is the extremely high price. A ton of coal will buy a pair of shoes, whereas at one time it required three or four tons. The price of coal, however, is largely psychological, in that the market has been made by excited and more or less careless bidding, while the fact that coal is a particularly essential commodity has had an important influence.

Again, as to "labor" there has been much complaint. The supply of labor has been insufficient, but the matter can be put the other way, that there is an excess of desire to employ labor. Then there is complaint as to remuneration, that some vocations that require "years of preparation" do not furnish as good pay as the pick-and-shovel man gets, but the latter may rejoin that some people could prepare all their lives and then not have acquired the kind of back necessary for pick-and-shovel work.

One man tells us that money rates are too high, while another tells us that costs are so high capital will not seek investment. Both cannot be right. Everyone has his own complaint. Yet we have had the free play of forces for twenty-one months, since the Armistice, and really it is rather a strong demand upon us to admit that nothing has been adjusted or settled or equalized in that period. If collectively we have accomplished scarcely anything in nearly two years, a great many of us are likely to die before all the adjustments have been made. It would seem better to cultivate contentment with the circumstances forced upon us, to endeavor to complain less, and to make more effort at individual progress, taking things as they are, even though they are different from conditions before the war or conditions we expected to obtain after the war.

Where Are The Chemists?

UNDER the caption "How Best to Serve" appears an interesting editorial in the August *Journal of Industrial and Engineering Chemistry* which may be taken to express the attitude of officials of the American Chemical Society toward the movement leading up to the Federated American Engineering Societies. It is in answer to the question "Where are the chemists?" propounded in the June 23 issue of *CHEMICAL & METALLURGICAL ENGINEERING*, and is to the effect that the American Chemical Society actually is now functioning in public affairs by passing resolutions, by its officials' testimony before Congressional committees and advice to Government bureaus, and by the issuance of a news service recounting chemical facts in non-technical language. Past achievements convince the officers of the Society that they can continue to do good work all by themselves, without incurring the expense of affiliation in a national organization.

It is possibly due to obscure writing that the editor of the *Journal* has apparently missed our point. More simply stated, it is this: The new Federation is to be composed of engineering and allied technical organizations. Incontestably there is a big work to be done by it in furthering the public welfare wherever technical knowledge and training are involved. Where are the

chemists? Such large numbers of them are engineers or engaged in work so closely related to engineering that it seems to us the officials of the Chemical Society are overlooking the inter-relationship of this new forward movement with chemical progress. A formal invitation to join has been extended to the American Chemical Society in common with all others of related interest and no doubt will receive careful consideration before an official reply is made.

Manufacture of Aluminum Castings

A SERIES of comprehensive papers by R. J. ANDERSON discussing the manufacture of aluminum: copper alloys starts in the present issue of *CHEMICAL & METALLURGICAL ENGINEERING*, in which debatable points in the practice are discussed in the light of experimental results. As may be known, the so-called No. 12 alloy (containing about 92 per cent aluminum and 8 per cent copper) and other light aluminum: copper alloys for sand castings are manufactured by two distinct methods: First, by adding solid copper to liquid aluminum in the required proportions by weight, and second, by charging a copper-rich alloy with the purer aluminum.

Many kinds of rich alloys are employed in non-ferrous alloy metallurgy, including phosphor-tin, phosphor-copper, manganese: aluminum, manganese: copper, silicon: copper, nickel: copper, and copper: aluminum, for making fixed additions of elements in the manufacture of alloys. Similarly, in alloy-steel metallurgy, such well-known ferro-alloys as ferrotungsten, ferrochromium, ferrosilicon, ferromanganese, ferrovanadium, ferromolybdenum and other minor iron-alloys are employed for particular purposes. A rich alloy is employed for one or both of two purposes: First, for deoxidation or scavenging, and second, for making fixed additions of certain elements in the manufacture of alloys. From the metallurgical standpoint, rich alloys are generally preferred to commercially pure ingot because such alloys can usually be made with such melting points that they are readily incorporated in a bath of liquid metal. Furthermore, the liability of oxidation and slag losses of valuable metals is less.

Contrary to such general ideas ordinarily held by foundrymen about rich alloys, some foundries casting No. 12 alloy make the alloy by simply charging light copper punchings into a bath of liquid aluminum, hotter than usual, but still far below the melting point of copper. The copper alloys with the aluminum partly by diffusion and partly by solution and the rate of alloying is therefore dependent upon many conditions. A number of foundries in the United States employ this method exclusively, while many others decidedly oppose it on the ground that it is unsuitable for commercial practice. It certainly requires the bath to be superheated at some portion of its history, a practice which is quite liable to induce blow-holes and sponginess in the resultant castings. Some of the casting losses have been attributed to this method, it being claimed that, because of non-homogeneity of successive heats and even of a single ill-mixed melt, the castings are liable to run "hard and soft."

In view of the rapidly expanding use of aluminum castings, such a discussion of practice with recommendations for its improvement as will be presented by Mr. ANDERSON should be very interesting to metallurgists and foundrymen engaged in this work.

The Functions and Training Of the Chemical Engineer

MANY attempts have been made to define in a few words that branch of applied science which is known as chemical engineering. That such efforts have not been entirely successful is due largely to the fact that the profession is still in a formative stage of development.

The change in the training of the chemical engineer—from a mechanical engineer with a smattering of chemistry to a physical chemist with an engineer's point of view—has been brought about by a realization that chemical engineering is a distinct branch of engineering involving more than the mere adaptation of mechanical engineering principles to new environments. However, a clearer conception of many of the fundamental principles of the new science, of the chemical engineer's duties and of his true place in the industrial world will be necessary on the part of the instructing staffs in order that they may be qualified to train men for a profession which is destined to become one of the leading branches of engineering. That much remains to be done is evident from a recent statement that there are probably not more than six hundred qualified chemical engineers in the United States!

The question of chemical engineering education has received considerable attention lately, particularly in England, where the discussion on "What Is a Chemical Engineer?" at the May meeting of the Chemical Industry Club and the papers on "Functions and Training of the Chemical Engineer" by Lord MOULTON and Professor J. H. WEST of the Royal College of Science have brought out many interesting points. In order to encourage expressions of opinion or criticism from chemical engineers and others in this country, Professor WEST's views are set forth in full elsewhere in this issue.

In this paper it is clearly pointed out that there are different kinds of chemical engineers and that the duties of a chemical engineer in plant work vary somewhat with the size of the plant and the complexity of organization of the technical staff. The statement that the daily routine connected with the operation of a smoothly running plant is not real chemical work or chemical engineering may come as a shock to some. While the man who is constantly on the alert for ways and means of increasing the efficiency of the process for which he is responsible may be pardoned for taking exception to this statement, does it not apply with full force to the man who is satisfied when he has filed away the day's data sheets and made the necessary entries on the production records?

In the light of this and similar discussions, we may summarize briefly the requirements for a chemical engineer. He must first of all be thoroughly familiar with all types of standard equipment for carrying out chemical engineering operations. A knowledge of the changes in chemical and physical properties of materials with varying temperature, pressure and concentration is also essential in considering the design or material of construction to be used in apparatus for a particular process. He should know how to calculate and apply quantitative flow sheets for heat and materials. The chemical engineer should appreciate fully the possible effects of change of scale upon the smoothness of a process developed in the research laboratory or in the small-scale plant. While he should not be

expected to handle problems of a purely mechanical engineering nature, he should be sufficiently well versed in the fundamentals of this and allied engineering fields to be able to confer intelligently with experts in these branches. In this respect he should resemble the head of a large corporation who, although not an expert accountant, is able to tell his accounting department what is wanted and interpret its reports.

While all these phases of chemical engineering training are recognized today, it is doubtful whether a single educational institution could be found which is satisfied that its present course is so standardized that further improvement is unnecessary. Much progress will undoubtedly be made through suggestions from graduate chemical engineers who have learned through experience the weak points of the courses which they took. It might indeed prove profitable for departments of chemical engineering to keep in touch with their more experienced graduates for the purpose of strengthening their curricula through the constructive suggestions of these men, who are in the best position to interpret the needs of industry.

Auto-Catalytic Improvement

WHEN the Interstate Commerce Commission practically embargoed all other freight by giving open-top car priority to coal it did not at once appear that this remedy was to prove as quickly effective as now seems likely. The process of improvement in the fuel supply of the country, however, seems to have been catalyzed twofold by this arrangement. In the first place, coal, having priority, moves first, last, and all the time. In the second place, other raw materials and products requiring open-top cars do not move at all adequately to permit industrial activity on a full scale. As a consequence much construction work and many industrial activities, finding a shortage of cars, are unable to operate at all or must do so at part capacity. Their coal requirements are immediately reduced by this decrease in activity. The secondary effect of the order, therefore, is perhaps even more important in relieving the apparent fuel shortage in all markets than the primary relief. It is to be hoped, however, that this secondary effect will not progress too far and result in extreme curtailment of industrial activity. If it does we may well expect the cure to be almost as bad as the disease which the I.C.C. is treating.

Interrelation Of Sciences

THE untimely death of Surgeon-General WILLIAM C. GORGAS again reminds us of the important relation of one science to another. Without the wonderful work of this famous officer in the field of sanitation, much of the American success in cleaning up Cuba would have been impossible. His work as the chief sanitary officer in the Panama Canal Zone was, too, a fundamental contribution of greatest importance to this engineering project. Any who are disposed to exaggerate the importance of their own science can well consider this case and realize that it is only by adequate co-ordination of chemistry with engineering, chemistry with sanitation, chemistry with physics and mathematics, chemistry with biology and medicine, that the greatest accomplishments of the chemical profession may be achieved.

Readers' Views and Comments

Intercrystalline Brittleness

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have just been reading Technologic paper 158, of the Bureau of Standards, dealing with "A Peculiar Type of Intercrystalline Brittleness of Copper."* This is an interesting paper and there is food for thought in the following remark taken from page 5:

It may be assumed, therefore, that only a relatively very thin skin has been rendered brittle by the electrolytic action; the properties of the entire rod have, however, been very profoundly changed.

At various times I have given some thought to the phenomenon of brittleness due to the action of sulphuric acid, on an iron bar, for example. It has often occurred to me that here is merely a surface action and yet, as is stated, the entire rod is "profoundly changed."

It seems inconceivable that any extensive alteration of the interior of the rod has occurred. Would it not then be possible that this brittleness is an electronic phenomenon, which might be described as a change in surface tension? In other words, may not the molecules of the metal be held together through surface action or tension, in effect binding the mass of material together, as the mass of molecules is held together in a drop of mercury?

While the placing of a bar of metal in a lathe and shaving it down does not alter this cohesion of the surface, yet some chemical action due to acid or alkali or to occluded gases might impair this skin effect, as has been so well described in circular 158 mentioned above.

Maybe we shall some day revise our views with respect to the forces which hold the particles of masses together.

Balanced Reactions in Steel Manufacture

To the Editor of Chemical & Metallurgical Engineering

SIR:—George F. Comstock has called my attention to a contradiction which I readily acknowledge in my paper "Balanced Reactions in Steel Manufacture," published in your issue of April 7, 1920. He writes:

"In the fifteenth line of the first column on this page it is stated that with much FeO in solution the ratio of CO₂ to CO will be great. But in the eleventh line from the bottom of this same column it is implied that this ratio should be higher with less FeO in solution. Is there some error here, or can you explain how these two statements can both be true? It seems to me that the 'CO₂ : CO ratio' in the tenth line from the bottom, and also in the little table, fourth line from the bottom, should really have been written 'CO : CO₂ ratio.'"

In the second paragraph of course the ratio CO₂:CO should read CO : CO₂.

Since writing that paper, however, I have found that the method of Goerens for estimating the gases in steels is liable to serious error. His method is based on fusing steels in a mixture of metals in which these gases do not dissolve and measuring the volume of gas

which is evolved. The carbon in the steel sample cannot be dissolved either, and it rises to the surface of the molten mixture, where it reduces any CO₂ to CO, so that the total volume of gases is probably correct considered as an equivalent in CO, but the proportion of CO to CO₂ is entirely altered and no longer represents their relative ratios when present originally in the steel.

This vitiates any conclusions based on such results and makes my statement referred to one which may be true, but is not yet supported by any experimental evidence.

I would rather withdraw the paragraph entirely until figures to support it or disprove it can be obtained.

Shattered Zones in Rails

To the Editor of Chemical & Metallurgical Engineering

SIR:—Editorial correspondence appearing in your issue of June 30, reviewing papers presented at the recent meeting of the American Society for Testing Materials, devotes some space to my observations concerning shattered zones in steel rails. If it is important to give credit to those who have advanced the subject, I should be inclined to state the matter differently than you have on page 1,189.

Messrs. Waring and Hoffmann at the very outset announced the presence of shattered zones in new rails; therefore it was not reserved for any one else to prove their pre-existence. What Waring and Hoffmann found, others have of course also found.

The high points in the investigation of shattered zones comprise:

1. Their presence in the heads and at junction of web and base in both new and used rails.
2. Hot sawed ends do not show shattered metal.
3. Certain medium hard rails have not yet been observed to display such zones, which, on the other hand, have been found in hard steel rails and wheels.
4. No foreign inclusions have been found in the shattering cracks.

Item 2 fixes the time of their formation in the stage of cooling after hot sawing. Curing by hot sawing is contrary to all known principles.

So many irrelevant and untenable conjectures have been made regarding transverse fissures that it has not seemed worth the while to discuss those on which there seems no basis of support. However, I think all tangible suggestions have been looked into. The reason for an interior origin of a fissure I think I stated clearly in 1911, arguing from a principle of mechanics.

\$1,000,000 Louisiana Oil Plant

About \$1,000,000 will be the cost of a plant for manufacturing essential oils to be built at Bogalusa, La., by the Essential Oils Co. of Philadelphia. The company has contracted to obtain its supply of wood waste from the big mills of the Great Southern Lumber Co. At least 500 men will be employed to operate the oil works.

Some Theoretical Principles of Alloying

A Discussion of Possible Applications of Such General Concepts as May Be Drawn From the Equilibrium Diagram, Heat of Alloy Formation, Thermit Reaction, Diffusion and Solution to Problems Connected With the Production of Aluminum : Copper Alloys in the Foundry

BY ROBERT J. ANDERSON*

IN A detailed discussion of the manufacture of aluminum: copper alloys—except aluminum bronze—it is desirable to commence by a brief presentation of the equilibrium diagram for the Al:Cu system, as well as the effects of heat of formation, thermit reaction, diffusion, convection and solution. In the commercial preparation of metallic alloys the influence of various factors may be overlooked, but a thorough understanding of the fundamental metallurgical principles of alloying will permit corrective measures to be applied more readily when foundry troubles, due to the alloy, arise.

EQUILIBRIUM DIAGRAM

The aluminum: copper series of alloys is of interest to the non-ferrous metal industry because it embraces many light castings, the rich alloys used for introducing copper into aluminum, and also the so-called aluminum bronzes. The curve shown in Fig. 1, after Carpenter and Edwards,¹ agrees well with that published by Guillet, except in minor details. With reference to this diagram foundrymen are interested mainly in the alloys containing 2.0 to 14.0 per cent copper, in those containing 33.0 to 60.0 per cent copper, and in those of aluminum: bronze composition, i.e., about 90.0 per cent copper and 10.0 per cent aluminum.

Three intermetallic compounds are known, viz., Cu₂Al, Cu₃Al and Cu₉Al. An investigation with regard to the solubility of Cu₂Al in aluminum at different temperatures has recently been carried out by Merica² and his collaborators. These investigators have found that the solubility of Cu₂Al in aluminum decreases with decreasing temperature from about 4.0 per cent at 525 deg. C. to about 1.0 per cent at 300 deg. C., and it is less apparently at still lower temperatures. This means that the line dropped from *k*, in Fig. 1, to the base should not be perpendicular, but it should curve in accordance with the temperature-solubility of Cu₂Al. Detailed discussion of the diagram is not necessary, nor will information as to equilibrium between the phases of the alloys be germane to the present article, but the diagram will be found useful for reference.

It may be emphasized, however, that not many alloys as commercially cast are in final equilibrium as indicated by their diagrams, and very fast or very slow cooling may be required to produce an alloy in true equilibrium. In fact, it is rather generally true that alloys are not usually in equilibrium unless actual pre-

cautions have been observed to insure this condition. The properties of alloys are influenced by this deviation, and the interpretation of phenomena which occur in alloys will be easier if this deviation from equilibrium is borne in mind.

HEAT OF FORMATION

When alloys are formed from their components the union takes place either with a development or an absorption of heat, but the possibility that other reactions may affect the heat change should not be overlooked. Few calorimetric determinations of the heat changes occurring in the formation of alloys have been made, but some are due to Person,³ and Richards and Forbes,⁴ and in the case of aluminum: copper alloys to Longuinine and Schukareff.⁵ Direct estimation of the heat of solution (formation) of alloys is practicable only with metals and alloys of low melting points, and the difficulties involved in determinations of metals of high melting points are almost insuperable. The indirect method of determining the heat of solution consists in measuring the amount of heat developed when an alloy is dissolved in a liquid chemical reagent and then comparing the result so obtained with the heat calculated (for an alloy of the same chemical composition) from the observed heats of solution of the component metals dissolved in the same chemical reagent. If the measured heat of solution of the alloy is less than that calculated by the rule of mixtures, then the difference is said to represent the heat developed in the formation of the alloy. If the observed heat of solution is greater than that calculated the difference represents the heat absorbed. This method for determining the heat of solution of alloys was originally carried out by Hess, and has been employed by Galt and Baker in determinations of various alloys.

In the experiments of Longuinine and Schukareff the heats of formation were determined by measuring the heat of solution of aluminum, copper, and alloys of the metals in aqueous solutions of bromine and potassium bromide. These investigators found that an alloy corresponding to the formula Cu₂Al had the greatest heat of formation, but no such intermetallic compound exists; hence, the validity of their results is somewhat conjectural. The subjoined figures for the heats of formation of alloys of aluminum and copper are from the work of these investigators; most of the compositions given do not correspond to known intermetallic compounds.

Baker's experiments⁶ indicate that the greatest heats of formation in the copper: zinc system occurred in the

Compo	Calories	Calories	
Cu ₂ Al	123.5	CuAl	20.8
Cu ₃ Al	137.9	Cu ₂ Al ₃	48.9
Cu ₄ Al ₃	71.0	CuAl ₂	57.2

intermetallic compounds; it is to be expected that the same would be true of the aluminum: copper system.

Entirely satisfactory figures for the heat of formation of various alloys of aluminum and copper are not available, but there is sufficient evidence to show that part of the rise in temperature which occurs when the two metals are alloyed is due to this phenomenon. It is a well-known fact that when aluminum is added to liquid copper there is an appreciable and immediate rise in temperature, but some disagreement has existed as to whether this temperature rise should be ascribed to heat of formation or to a thermit reaction between the aluminum and the oxygen in the copper.

THERMIT REACTION

The possibility of reactions other than heat of formation contributing to the heat change observed when aluminum is added to liquid copper, or *vice versa*, has been mentioned. Ordinarily when aluminum is added to liquid copper there is a rise in temperature which, according to some observers, is from 40 to 250 deg. C., and often, according to others, sufficient to raise the temperature of the liquid melt to an intense white heat. The available evidence appears to indicate that this should not be attributed solely to heat of solution of

aluminum in copper, as has been done,⁷ but rather in part to the interaction of aluminum and copper oxide, or to aluminum and oxygen, or both. This is a strongly exothermic reaction. The reasons for the rise in temperature observed when aluminum is added to liquid copper have been gone into rather thoroughly in the discussion of the work of Carpenter and Edwards,⁸ who found that when aluminum was added to liquid copper a very marked evolution of heat occurred; they did not find, on the other hand, any great rise in temperature

FIG. 1. EQUILIBRIUM DIAGRAM OF THE ALUMINUM: COPPER SYSTEM (AFTER CARPENTER AND EDWARDS)

provided the copper had been properly protected from oxidation. The conclusion was that the rise in temperatures should be attributed, not to the combination of aluminum and copper, but to that of aluminum and oxygen. Other investigators have found that if just sufficient aluminum is added to reduce all the copper oxide present⁹ in a melt of oxidized copper, subsequent additions of aluminum will not produce any considerable rise in temperature.

FIG. 5. CuAl₃ (light) and eutectic (dark), from one of the bands in Fig. 4; etched with NH₄OH + H₂O₂; $\times 200$.

Experiments carried out at the Bureau of Mines have shown that there is always a rise in temperature when aluminum is added to liquid copper, due to the heat of formation of the resultant alloy, but that the large rise in temperature described as a "white heat" is due mainly to the thermit reaction of aluminum with copper oxide. This large rise in temperature is very destructive of crucibles and iron pots in foundry practice, and it can be guarded against by melting the copper under a charcoal cover (if badly oxidized copper is used), by deoxidation with boron suboxide, or by otherwise preventing the oxidation of high-grade copper. The question of both heat of formation and thermit reaction in connection with the manufacture of aluminum: copper alloys is highly important as affecting dross losses.

There is plenty of evidence to show that the diffusion of metals in the solid state is a very general phenomenon, the classical experiments of Roberts-Austen¹ being particularly well known. That one solid metal can dissolve another has been shown by maintaining carefully surfaced pieces of two different metals in intimate contact for a long time. At atmospheric temperatures the diffusion is very slow, but it becomes more rapid at higher temperatures; and if a solid metal of higher melting point is placed in a liquid metal of lower melting point diffusion may be extremely rapid, depending upon the individual metals, the size and shape of the immersed metal, the relation of volume of liquid metal to surface of solid metal exposed, rate of agitation, amount of convection and the temperature.

From the practical standpoint diffusivity figures are not of much value, and furthermore they are liable to be in error when determinations are made of the diffusion of solid into liquid metals because of the effect of other factors such as convection, solution, and the changes occurring during alloying where the liquid metal is becoming progressively richer and richer in the solid metal. The object in calling attention to these factors is to indicate that they must be considered in the manufacture of alloys, but diffusivity figures in themselves are not necessarily applicable to foundry practice.

The process of diffusion may be conveniently observed (in the case of copper and aluminum) by placing a rod of solid copper in a crucible of liquid aluminum for a short time. On withdrawing the rod a fairly adherent coating will be found, consisting of a brittle silvery-colored alloy rich in aluminum. On analyzing the metal remaining in the crucible varying amounts of copper will be found, depending largely upon the time period of immersion of the copper rod and upon the temper-

FIG. 4
Micrograph of diffusion of copper into aluminum; etched with NH_4OH + H_2O_2 ; $\times 25$.

ature. If a microsection of the alloyed rod be examined, varying structures will be found, depending upon the thickness of the coating. Figs. 2 and 3 show the diffusion of copper into aluminum. The white areas above the black band separating the copper (below) and the aluminum: copper alloy (above), correspond to copper-rich compositions; the characteristic rectangular structure of CuAl is shown, and the alloy becomes leaner in copper with increasing distance from the copper. These micrographs were taken on a sample obtained by suspending a cylinder of solid copper in liquid aluminum for a short time at a temperature below the melting point of copper and then freezing the aluminum with the copper in place. Fig. 4 is a view taken across an area of a diffusion sample obtained by freezing a copper rod in liquid aluminum after suspending it for five minutes at 700 deg. C. Starting with copper at the lower band in Fig. 4, the changes in microstructure from bottom to top of the photograph illustrate the variation in copper content (copper becoming leaner in the alloy with increasing distance

from the copper rod). Fig. 5 shows the microstructure of one of the bands in Fig. 4; the structure corresponds to an alloy of about 55.0 per cent aluminum and 45.0 per cent copper in composition. The delta constituent, CuAl , appears light, since it is electronegative to the eutectic. The diffusion of metals may also be shown well by making small superposition ingots according to the method of Le Chatelier or otherwise. The principle of filiation,² enunciated by Le Chatelier in 1900, consists in the superposition of two metals in the liquid state in the order of their densities. The diffusion of one metal into the other makes it possible to obtain in a single specimen the entire series of alloys which can be formed by the metals. The series of alloys ranging from one pure metal to the other will be confined in a relatively restricted area, and the width of the area will depend upon the length of time during which one or both metals were liquid, upon the rate of cooling and upon the amount of agitation. While the preparation of superposition ingots serves a useful demonstrative purpose, it has a rather well-defined limitation in studying alloys. Fig. 6 shows the superposition of aluminum and copper, according to Le Chatelier.

FIG. 6
Superposition of aluminum and copper (after Le Chatelier).

Convection currents in melting pots hasten the solution and diffusion of copper in aluminum—for example, in the manufacture of No. 12 alloy by charging copper punchings into liquid aluminum. There is more or less convection in any vessel heated over part of its external surface, and both diffusion and solution are more rapid with increased convection.

Convection is not to be confused with agitation, but the latter also hastens diffusion and solution. The importance of agitation by frequent stirring was early recognized in German practice, where charges of liquid aluminum and solid copper were stirred for several hours so as to insure thorough alloying. However, there is no necessity for stirring for such long periods.

SOLUTION

Copper forms a compound, CuAl_2 , with aluminum, and this compound has a limited solubility in aluminum in the solid state, the solubility varying with the temperature. The fact that copper may be alloyed with aluminum when solid copper is placed in liquid aluminum at a temperature considerably less than the melting point of copper is ascribed to the combined influence of solution and diffusion. Both factors are affected by temperature, and the rate of both solution and diffusion is more rapid at, say, 900 deg. C. than at 700 deg. C.

Production of Potash in the United States*

Incomplete returns thus far received by the Department of the Interior indicate that 110,309 short tons of crude potash salts, containing 30,899 short tons of available potash (K_2O), valued at \$7,889,440, was produced in the United States by 73 firms in 1919.

In 1918 there were 128 firms operating plants, which produced 207,686 short tons of crude material containing 54,803 short tons of available potash. In 1917 only ninety-five firms were operating plants, which produced 126,961 tons of crude material containing 32,573 short tons of potash.

PLANTS REOPENED

More than 60,000 tons of domestic crude potash material was in storage in January, 1919, and most of the plants were closed for a part of the year, some of them for the larger part. These conditions were brought about by the expectation of large imports of potash salts from abroad—an expectation that was not realized. Instead the stored material was sold, and many of the

	4	1,616	622	5.2	146,720	26.51
	43	42,008	11,969	100	\$2,738,195	

plants were reopened in the autumn, though some of them were again obliged to stop work because of shortage of coal.

The potash produced in the United States during the first three months of 1920, as reported to the Geological Survey from forty-three plants, amounted to 42,008 short tons of crude material containing 11,969 short tons of available potash, valued at \$2,738,195.

NATURAL BRINES

The only notable gain seems to be an increase in production from natural brines elsewhere than in western Nebraska. In 1919 six plants that produced potash from these brines made an output of 11,293 short tons of potash. In the first quarter of 1920, five plants working the same brines produced 4,104 short tons of potash, and if they continued production at the same rate during the entire year they would produce 16,416 short tons. The production of potash from cement kilns is proceeding at almost exactly the same rate in 1920 as in 1919, although there were only seven producers in the first part of 1920, against 13 in 1919.

Alunite was used in 1920 only in experiments made by companies that reported production of potash from this material in 1919.

The accompanying tables were compiled by M. R. Nourse.

British Columbia Plans to Develop Its Iron Deposits

Plans to establish an iron and steel industry on the Pacific coast of British Columbia are being considered by Canadian interests. Deposits of magnetic iron ore are known to exist in the territory, together with the necessary flux and fuel. The Canadian Collieries, with its extensive coal fields on Vancouver Island, its coke ovens and iron-ore-bearing properties, is probably better situated than any other corporation to undertake this important project.

Already a group of engineers has been in consultation with the government authorities, to establish ways and means of erecting a 300-ton furnace. It is felt that there is enough demand for iron and steel in the district to take care of the output of such a furnace, and if this demand does not materialize, the establishment of railroad car and equipment shops in this section would solve the difficulty.

Government co-operation is assured in the form of bonuses for pig iron in British Columbia produced from local ores. For a 300-ton plant this would amount to about \$1,000,000 yearly.

Progress in the Byproduct Coke Industry*

Description of the Modern Practices and Methods Exemplified in the Ford Plant—Coke-Oven Gas—Market for Byproducts—Ammonium Sulphate—Light Oil and Gas Enrichment—Tar

By C. R. BELLAMY

THE year 1919 is memorable to the coke industry in the United States, for in it for the first time the production of byproduct coke exceeded that of beehive coke. This fact is at the same time of vital importance to all our industries. For as Foyd Parsons has expressed it, "The industrial prosperity of leading civilized nations depends upon their utilization of fuels and metals." In this statement is found the real significance of the change from beehive to byproduct coke predominance. Better utilization of coal, our basic fuel, is the beginning of real conservation.

Our byproduct coke-oven industry, with close to 11,000 ovens in operation at this time, is one of huge dimensions, and the modern coking plant is one of the great achievements of chemical and mechanical engineering. The results of a modern plant show what progress has been made. The high yields indicate improved methods, while the uniform yields indicate the extent to which operation is under control. A better knowledge of the factors that are essential to good results, coupled with the ability to control these conditions, is the feature of our best plants. Before going into details concerning operation data of one of the most modern plants let us briefly trace the growth of this industry and the progress that has kept pace with this growth. In the writer's opinion, the expansion of the byproduct coke oven has been marked by three distinct periods, which with the attributed causes are given in order of sequence:

1. Recognition by the steel industry that byproduct coke could be made that was superior to any beehive coke.

2. Recognition by the gas industry of the fact that in the byproduct coke oven was its opportunity for development on the lines of real efficiency and economy.

3. General conviction that the market for benzol, ammonia and tar was firmly established and able to absorb all possible production from coke ovens.

The first period was realized by overcoming the old-time prejudice of the blast-furnace operator and then seeking his co-operation in determining what constituted a satisfactory metallurgical coke. To illustrate this, the work of the Semet-Solvay Co. in conjunction with that of different blast furnaces is most interesting. For years this company made daily all the tests of which it had knowledge, such as specific gravity, porosity, shatter, loss in CO_2 , size of pieces and structure. These tests, accompanied by investigation and research at ovens and furnaces, finally led to the fixing of certain definite standards, and by strict adherence to these standards byproduct coke has come to sell at a premium. Factors which are considered essential to the production of high-grade furnace coke are:

1. Proper preparation of the coke in all respects, including size.

2. Uniformity of the coal mixture used in the manufacture of coke, thereby producing coke of reliable chemical composition.

3. Uniformity of heating of the charges in the oven, thereby controlling the physical structure of the coke.

COKE-OVEN GAS

The commercial value of the surplus gas from byproduct coke ovens was slow to be appreciated, and it was only about eight years ago that any general recognition of this value was apparent. Since then the progress in this direction has been so remarkable that today the byproduct oven looms up as the real solution to the problems confronting our public gas utilities. Very many of the large cities east of the Mississippi River are now supplied with coke-oven gas straight or mixed with water gas. The literature of the gas industry as concerns manufacture is now largely devoted to the byproduct oven and it has given us many valuable papers upon this subject.

In this field, again, co-operation has meant success. Joint investigation by the two industries concerned has made it possible for the modern byproduct plant to deliver a coal gas that will pass the most exacting specifications as to B.t.u., candle power and purity. And this gas can be produced so economically that no other process can compete. Some of the factors that make the production of such high-grade gas possible are:

1. Proper mixture of proper coals.
2. Tight ovens.
3. Proper regulation of pressure in ovens and in the hydraulic mains.
4. Proper carbonization temperatures.
5. Constant and reliable observations.

MARKET FOR BYPRODUCTS

During the world war the byproducts from coke ovens were found to be indispensable. Because of their exten-

FIG. 1. PUSHER SIDE OF OVENS, LIGHT OIL PLANT IN FOREGROUND

*Read before the American Institute of Chemical Engineers, Montreal, June 29, 1920.

sive application at that time the merits of these products are now appreciated to the extent that they are just as indispensable in times of peace. As soon as this market was established the coke and gas industry was quick to avail itself of the fact and the growth of the industry has been very rapid since then (1914).

The byproducts are the same now as before the war, although at that time the Semet-Solvay Co. was the only commercial producer of light oils. Improved methods have, however, resulted in much better yields of these products. This improvement consists chiefly in the control of operating conditions. There is an old coke-oven axiom, "Temperatures, incident to the so-called

FIG. 2. PUSHER SIDE OF BATTERY

high-speed operation, seriously affect the yields." Under modern practice this has been changed so that it can be said that temperatures properly related to the speed of operation do not seriously affect the yields. And likewise the other determining factors are now under regulation.

THE FORD PLANT

The modern practices and methods are well exemplified by the plant of the Ford Motor Co. at River Rouge, Mich., which is considered by many to be the finest byproduct coke-oven plant in the world.

Early in May it was my good fortune to study this plant for several days, and in this article I want to discuss certain features of the equipment, operations and results which particularly impressed me. The data given here are those of actual results. The yields are especially important, not only because they are high but because of their uniformity through varying speeds of operation.

This plant was completed and put in operation in October, 1919. Its chief function is to supply a high-grade metallurgical coke to the Ford blast furnaces. At the same time a contract with the Detroit City Gas Co. calls for 10,000,000 cu.ft. of 18 cp. and 600 B.t.u. gas per day. Thus these ovens constitute a combined coke and gas plant and must maintain the highest quality in both products. To do this the speed of operation must not give rise to conflicting factors, but rather all conditions must be properly co-ordinated to the speed of operation. Due to the unsettled conditions in the coal and railroad industries this plant has not had any really fast operation. In fact, very few plants have operated at full capacity during the period under discussion. The operation, however, has been performed at somewhat varying speeds, so that a study can be made of the effects, if any, of such changes.

The Ford plant consists of 120 standard Semet-Solvay regenerator coke ovens, built in two batteries of equal size. Each battery is independent of the other in regard to control of operation. The gas direct from the ovens is received by a double hydraulic main, one main taking the rich gas given off during the first period of carbonization, while the second main receives the remaining lean gas. This separation of gas during carbonization is performed in the usual manner—that is, by valves which are easy to open and close and which can be reversed when and as often as desired. The rich gas and lean gas are treated exactly alike up to the benzol scrubbers. Here the treatment is different and after passing through these scrubbers the two gases travel different paths, the lean returning to the ovens, the rich gas after enrichment and purification going to the city. The apparatus and equipment used to handle the gas is built in triplicate, one unit for the rich gas, one for the lean, with the third and middle unit as a spare. This spare unit is so connected to the system that it can take care of either the rich or lean gas as necessary. The importance of this feature is that repairs, apparatus cleaning and inspection do not cause inefficient or irregular operation. Having a spare system of byproduct recovery apparatus and a spare for all essential machinery used on the ovens, this plant is enabled to operate on a timetable schedule. Every oven is pushed at the exact time scheduled, the schedule being observed with railroad precision. This regularity of operation which is essential to the production of a satisfactory quality of surplus gas, where high standards are required, means also that the load on byproduct apparatus is uniform and favorable for maximum byproduct yields. In the table of results it will be noted that the initial rich gas has

FIG. 3. DISCHARGE SIDE OF OVENS AND COKE WHARF AT LEFT

been produced without an appreciable variation in B.t.u. value for over three months.

Each oven is designed for a charge of fifteen tons of pulverized coal and to carbonize this coal in any period from 16 to 30 hr. as desired. The capacity of the oven and the uniform coal charges are points that are worth emphasizing. At the Ford plant not only is the daily average charge per oven uniform but there is very little variation in the weights of coal charged in the different ovens. The regularity maintained in this operation is shown by Fig. 4, which gives average daily weight of coal charged per shift. This curve is posted in the foreman's office and closely watched by all three shifts.

The size of an oven is determined by the amount of coal that it can successfully carbonize. Size has so far been an index to the progress of the industry, increasing capacity resulting in lower unit costs. This because the plant, exclusive of ovens, and force required for operation and maintenance of complete plant are fixed and independent of oven capacity. That is to say, the power plant, byproduct recovery apparatus, piping and other machinery will be practically the same for any given plant regardless of the capacity of its ovens, while

FIG. 4. OPERATING DATA, FORD PLANT, AVERAGE NUMBER OF POUNDS OF COAL CHARGED PER OVEN PER SHIFT

the number of workers will be almost the same. The increased tonnage due to larger capacity of units will therefore give its yields at little or no cost of production.

Operating on an 18 hr. schedule the Ford plant has a daily capacity of 2,400 tons of coal. Were these ovens of 12-ton size the capacity of the plant on a like schedule would be 1,920 tons. In a 30-day month this would mean that the 15-ton unit plant would carbonize 14,400 more tons of coal than the smaller unit plant. The yields from this increased tonnage would be about 10,000 tons of coke, 345,000 lb. of ammonium sulphate, 45,000 gal. of light oil, 115,000 gal. of tar and 86,000,000 cu.ft. of surplus gas. Figuring that the value of the coke recovered would cancel the cost of the additional coal and cost of producing byproducts there would be a net gain something like this:

345,000 lb. (NH ₄) ₂ SO ₄ @ 5c. per lb.	\$17,250
45,000 gal. light oil @ 15c. per gal.	6,750
115,000 gal. of tar @ 4c. per gal.	4,600
86,000 M. cu.ft. gas @ 20c. per M.	17,200
Total monthly gain.....	\$45,800

It is true that the initial cost of the larger plant would be greater, but the returns just enumerated would yield handsome interest on the additional capital required.

AMMONIUM SULPHATE

The recovery of ammonia at the Ford plant is performed by the Semet-Solvay direct ammonium sulphate process. This process, which represents over eight years' extensive experience with direct methods, marks a notable achievement in chemical engineering. The process is direct in procedure, practically automatic in operation and produces a pure white salt. The high yields which are obtained are readily explained by the direct manner in which the gas is treated and by the control of the ammonia reactions.

In the first place, each oven is properly filled with coal, as previously described, so that favorable conditions exist at the start. The coke-oven gas upon leaving the ovens travels a short distance from the hydraulic main and then passes through a two compartment cooler.

From these coolers an exhaustor (Curtiss steam turbine) takes the gas and sends it under pressure through a tar extractor of the P. & A. type, then through another two-compartment apparatus, called an economizer, from which apparatus it goes to the saturator. The gas leaves the saturator minus its ammonia, is freed of acid and then cooled for benzol recovery. This is the full journey of the gas so far as ammonia is concerned.

The gas enters the two-compartment cooler at a temperature slightly above 80 deg. C. In the first compartment the temperature is lowered about 30 deg. C. and in the second compartment it is brought down to 30 deg. C. This temperature of 30 deg. C. has been found to be the critical one for proper condensation in conjunction with minimum effort for subsequent heating. The cooling medium is a weak ammonia liquor, which, traveling over grids counter-current to the gas, is very efficient. The strength of this liquor is maintained so that only a minimum amount of NH₃ will be absorbed in the cooling of the gas and the condensation of the light tars. Separation of the tar and liquor is effected in the coolers, which have a large base, by means of decantation. The tar is drawn off from the bottom and runs to a decanter, while the liquor entering the suction pipe of the pump at a higher point is sent through cooling coils and then back to the gas cooler. Each compartment of this cooler has its own circulation. A special constant level overflow device maintains a constant volume of liquor for circulation by carrying away an amount equivalent to that added by condensation and absorption of ammonia. Ammonia thus held in solution has to be

FIG. 5. BYPRODUCT PUMP HOUSE

liberated by steam and lime in a still, from which it returns to the gas at inlet to saturator. With this exception the process is "direct."

The Curtiss steam turbine, whose primary function is that of an exhaustor, serves in a threefold manner, for in pumping the gas it is at the same time an efficient tar extractor. Due to heat of compression, the gas leaves the turbine at 50 deg. C., or about 20 deg. C. higher than it entered. Thus the turbine is exhaustor, tar extractor and heater combined. The P. & A. tar extractor removes the last trace of tar.

From the tar extractor the gas goes to the economizer, where it is brought in contact with the liquor of condensation from the hydraulic main to pick up and restore to the gas some of the water of condensation and free ammonia; the gas leaving the economizer is at the proper temperature for the sulphate reaction.

FIG. 6. EXHAUSTER AND COMPRESSOR ROOM

The clean gas at 70 deg. C. enters the saturator, which contains sulphuric acid of 45 g.p.l. strength, that is, nearly normal acid. The saturated acid is lifted by means of an air ejector into a sludge tank in which crystallization takes place and the unsaturated acid drains back to the saturator. The salt goes to a centrifugal, where it is first dried and then washed with water. It is dumped from the centrifugal into barrows, weighed and conveyed to a large hopper, from which it is handled into storage by an overhead crane.

A small stream of fresh acid (60 deg. Bé.) flowing into the saturator keeps the strength at the proper mark. With acid of the proper strength and gas at the proper temperature objectionable crystal formation does not take place in the saturator. The small amount of crystals that are bound to form on metal surfaces are not permitted to accumulate. Once each day for a few minutes the acid strength is built up to 125 g.p.l. and thus all crystals are dissolved and a clean saturator is maintained.

The results obtained at the Ford plant are indicative of the progress that this process makes in ammonia recovery. The high yields as shown in the table of operation data were obtained from a coal mixture containing 20 per cent low volatile coal. From straight high volatile coal even higher yields may be expected.

As important as the yield of a byproduct is the cost of production. The unit cost is the test that tells the tale. During the month of April this plant produced over 1,500,000 lb. of $(\text{NH}_4)\text{SO}_4$ with an operating force of five men per 8-hr. shift and one foreman. This foreman also has charge of the light oil plant.

One of the most essential points in a direct ammonia sulphate process is clean gas. Practically all the treatment through which the gas passes preparatory for entrance to saturators is made with the one purpose of obtaining clean gas. Upon the success of this treatment the purity and color of the sulphate depend. Hence the vital question is, "How clean is the gas?" To determine this the filter paper method devised by the Semet-Solvay Co. has been found very valuable. The apparatus, which is called the tar camera, needs little description other than that given in Fig. 7.

An apparatus is here shown by means of which a known volume of gas can be drawn through filter paper and a comparison made of the color produced on the filter paper to indicate the degree of purification of the gas. As usually performed two filter papers are used for each test to absorb the tar from 8 l. of gas.

The amount of tar carried by the gas should be reported by comparing these filter papers with a photo-

graphic scale, similar to that used in any color comparison quantitative test. Or where great accuracy is required the determination is made by weighing the filter papers before and after the picture.

This apparatus can also be used for the determination of H_2S in gas. In this test the filter papers used are, of course, moistened with lead acetate.

SURPLUS GAS

The method employed for the preparation for sale of the surplus gas from the coke-oven plant is determined by the specifications which the gas has to meet. The general trend in the industry is toward the elimination of candle-power specifications and lowering the calorific value of the gas required for cities. Canada has now permanently adopted a standard of 450 B.t.u. and no candle power. Only three of the larger cities of the United States still cling to a high-candle-power specification. This development is in direct line with the conservation of the natural resources of the country and is to the economic advantage of both producer and consumer of gas. It is no longer good economy to enrich gas with benzol to produce candle power when the requirements for motor fuel are rapidly outstripping the supply. Money spent for enrichment of gas is practically all wasted, as, with very few exceptions, the

FIG. 7. TAR CAMERA. LEFT—GENERAL LAYOUT OF APPARATUS. RIGHT—FILTER FRAME

consumer derives no benefit therefrom. The purchase of special coals or the separation of the rich gas from the lean, or any other operation involving cost, to increase the calorific value of manufactured gas brings no benefit to the consumer, who must, of course, pay for this increased cost, and the Public Service Commissions and gas manufacturers should join in the determination and adoption of the standard of calorific value which permits a million B.t.u. to be delivered to the consumer at the lowest price. Of course, gases containing high percentages of nitrogen, like producer

gas, are not to be considered in this discussion. This argument is illustrated by the following table, which shows the B.t.u. per cu.ft. in the various gases when mixed with the theoretical amount of air required for their combustion. This mixture of gas and air is what the consumer actually burns, so it is clear that any of these gases, when properly burned with the correct percentage of air, will give the same results.

	Natural Gas	Oil Gas	Retort Gas	Coke-Oven Gas	Carburized Water Gas	Blue Water Gas
B.t.u.	91	93	91.7	91	92	88
Flame temp., deg.	1,852	1,915	1,896	1,892	1,914	1,928

So the real point of interest to the consumer is which gas can be furnished to him at the lowest cost per million B.t.u.

In several cities, however, the legal standards still require the delivery of gas of high candle power and high B.t.u. content, and the gas from the Ford plant has to meet the standard of 18 candles and 600 B.t.u.

LIGHT OIL AND GAS ENRICHMENT

The recovery of light oil at the Ford plant is so closely related to the enrichment of gas that these two subjects can well be treated together. As is usual in plants where surplus gas of high calorific and candle power specifications is sold to public utilities, the rich and lean gases follow parallel but separate paths throughout the byproduct recovery system. Up to the benzol scrubbers they are treated exactly alike, but from here on the treatment differs.

It is a comparatively simple matter to obtain large yields of surplus gas that will pass the average B.t.u. requirements, which have recently been lowered in most states. In such cases it is possible to remove practically all the light oils from the gas, and if so the rich and lean gases can be treated alike in the recovery of benzol, or the gases may be treated without separation, if the calorific standard permits. In being freed of its light oil the surplus gas is lowered in B.t.u. value, but at the same time it has all of its naphthalene removed. This treatment gives a gas suitable for distribution and, if separated, of 590 to 600 B.t.u. value. Such a gas meets the requirements of many cities which retain a high calorific standard, but it will not pass a high candle-power specification, and where such exists it is necessary to produce a very high-grade gas. Proper oven operation will yield such a gas, after which this quality must be maintained and delivered to the city without loss. For distribution it is essential that this gas be free of $C_{10}H_8$, but it cannot stand the loss of any other illuminant. Of course, all the light oils could be washed out, freed of naphthalene and then used to enrich the gas to the proper mark. A high-grade gas would result, but the process would be rather inefficient and very

expensive. The correct way is to take out the $C_{10}H_8$ without removing the light oils. This is accomplished ratur and methods. The procedure is as follows:

The lean gas, upon leaving the saturator, is cooled and at the Ford plant by the standard Semet-Solvay apparatus enters the benzol scrubber at a temperature of about 25 deg. C. In this tall tower it is completely stripped of its light oil content by being washed with an absorption oil of like temperature. This absorption oil, straw oil or ordinary gas oil, is circulated counter-current to the gas flow and leaves the scrubber containing about 2 per cent of light oil.

The rich gas, upon leaving the saturator, is likewise cooled and enters a benzol scrubber at the desired temperature. Here it is washed by one-half of the benzolized absorption oil from the lean scrubber, the other half of this oil going directly to the light oil still. The

FIG. 8. DIRECT SULPHATE APPARATUS

small circulation of benzolized oil absorbs all the $C_{10}H_8$ from the gas, also some toluol and xyol, but removes very little benzol. Thus the gas is purified of $C_{10}H_8$ without serious loss of other illuminants. The drop in B.t.u. and candle power, due to this treatment, is so slight that very little enrichment is necessary. According to the latest figures, only 0.027 gal. of light oil is vaporized per 1,000 cu.ft. of gas to bring the gas above specifications.

The most important feature of this surplus gas operation is the uniformity of results. Not only has the surplus gas yield been high, as will be noted from table of operating data, but it has been a yield of high-grade gas. That is the important fact, for the yield of surplus gas means nothing until compared with the quality. Furthermore, this yield has been almost constant in amount through the varying speeds of operation. Every day from Jan. 1 to June 1 the gas company has received practically 10,000,000 cu.ft. of gas from these ovens—gas that has always been above the standard. This gas has been produced and delivered with scarcely any varia-

FORD OPERATING DATA, 1920

Surplus gas, light oil and tar yields

tion in B.t.u. or candle-power values. The uniformity of these results appears remarkable in comparison to those obtained only a few years ago, but shows what can be expected from modern ovens with advanced knowledge and methods for regulation. The maximum gas recovery which is here shown is one reason also for the uniformly high sulphate yield.

A description of the light oil still is hardly necessary, as it is of the standard Semet-Solvay type. No fractionation is made, but the light oil is purified, washed and redistilled and sold as motor fuel. A satisfactory motor fuel consisting of benzol, toluol and xylol, mixed with an equal amount of gasoline, has the following distillation results:

Boiling Point, 71 deg. C. Sp.gr. @ 16 deg. C., 0.811				
Off at, Deg. C.	Per Cent	Off at, Deg. C.	Per Cent	
85	10	114	60	
88	20	130	70	
91	30	154	80	
96	40	195	90	
103	50	218	95	

Loss on distillation, 2 per cent. Residue, 3 per cent.

During the switchmen's strike there was a gasoline shortage in Detroit which caused some worry but little or no inconvenience, due to the fact that the Ford plant was able to release 300,000 gal. of purified light oil for motor fuel. Tank wagons from the various companies came to a plant for oil and distributed it throughout the city. Thus a serious situation was averted.

The light oil that is recovered by the method described comes mainly from the lean gas. The true yield is therefore the sum of the oil produced and the oil left in the rich gas. This total would mean a high commercial yield, and one that would be possible wherever the gas specification was below 600 B.t.u., with no candle-power requirements.

TAR

The old-time problem, "What is to become of the tar?" has apparently been solved satisfactorily. With the enormously increased supplies the market has kept pace and today tar is selling at a decidedly higher price, but yet somewhat below its true value. Tar lends itself readily to a variety of uses, many of which are just beginning to be appreciated. The Ford experience affords an interesting illustration in this respect.

The original boiler equipment contained eight 400-hp. Wickes boilers, arranged for gas firing. The demand for gas was so heavy that tar was utilized in its place most satisfactorily and at a decided saving over coal, the value of tar being taken at 5c. per gal. When using tar the pump at the storage tank is run continuously, so that there is a constant circulation sufficient to meet the highest peaks and yet allow excess tar to be bypassed from the discharge to the suction line. In order to keep the tar hot the discharge line is wrapped with two 2-in. steam lines and the tar reaches the boilers at a temperature of 90 deg. C. At that point superheated steam is used to raise the temperature to 100 deg. C. and by means of steam injectors delivered to the tar burners.

When the price of fuel oil became almost prohibitory the Ford company began experimenting with tar to take the place of oil in the heat treatment of forgings, etc. This worked out so satisfactorily that the company expects shortly to be using 15,000 gal. of tar per day, which will do the same amount of work as the 25,000 gal. of fuel oil formerly used. Part of this is due to the higher efficiency of the tar and the remainder to improvements in operation. This tar is as it comes

from the byproduct coke plant, no further refinements being necessary.

In conclusion, I wish to acknowledge the assistance given by A. A. Kelkenney, superintendent of the Ford coke plant, in preparing the operation data and curves shown here and to express my appreciation of the courtesies and assistance given me by his organization.

The Solvay Co.
Indianapolis, Ind.

Progress in Low-Temperature Carbonization of Coal

Developments in the low-temperature carbonization of coal are taking place in the United Kingdom, and a number of important industrial concerns have entered into contracts to secure the products of this process. It is understood that three plants are to be operated in the execution of existing contracts, which contemplate the combustion of bituminous coal by low-temperature methods in order to conserve the potentially rich constituents, such as motor spirit or gasoline substitute, fuel oil, sulphate of ammonia, and gas. Among the industries which have recently made agreements to utilize the byproducts of the process are an electric power company, a large municipality, a firm of steel manufacturers, and a general manufacturing firm.

The exponents of low-temperature carbonization estimate that 1,000,000 tons of coal will be consumed annually under existing contracts and that plants for the exploitation of the process will supply, in addition to 7,000 million cubic feet of gas, the following products:

Products	Use	Approximate output for 8 per cent Ash
Motor spirit	Motor cars, aeroplanes	3,000,000
Fuel oil	Suitable for Navy and ship fuel	16,000,000
Smokeless fuel	Domestic fuel	700,000
Sulphate of ammon	Fertilizers and high explosives	9,000

It is understood that the process has been patented in this country and abroad. Although it appears that any important industry normally consuming large supplies of bituminous coal may utilize the process, the greatest development in its future exploitation will be through the erection of large plants in the colliery districts, where the constituents can be economically extracted and distributed.

Canada's Paper and Pulp Exports

The Canadian Government statistics for the year ended March 31, 1920, give the total value of the pulp and paper exports of the Dominion as \$104,636,901. This is the first time that these figures have reached the hundred-million mark. In 1919 the exports were valued at \$82,569,680, and in 1918 at \$63,344,143, the totals for the three years being made up of:

Paper and pulp	Year ended March 31		
	1918	1919	1920
Paper and in manufactures of			
United States	\$37,723,251	\$47,862,909	\$63,253,419
United Kingdom	32,768,348	38,621,265	50,367,339

The 1920 paper exports included 14,272,513 cwt. (713,625 long tons) of newsprint, valued at \$53,203,792, constituting more than 50 per cent of the total. The United States took 12,553,349 cwt. (627,667 long tons), valued at \$46,809,178.

Legal Notes

BY WELLINGTON GUSTIN

Decision on Patents of Cottrell and Speed

The United States Circuit Court of Appeals, Ninth Circuit, has reversed and remanded, with directions, the decree of the District Court, dismissing the infringement suit of the Petroleum Rectifying Co. brought against the Reward Oil Co. The suit was based on alleged infringement of the Cottrell and Speed patents, Nos. 987,115 and 987,116, for a process and apparatus for separating and collecting particles of one liquid suspended in another. The first-numbered patent covers the process and the second is for apparatus by which the process is carried out.

SPECIFICATIONS OF PATENT INVOLVED

The specifications in the invention say:

"There is a large class of oils that cannot be economically freed from water without distillation. These are largely oils in which the water is in very small globules, often less than one-thousandth of an inch in diameter, and behaving as if surrounded with a membrane-resisting coalescence of the drops . . . Many natural petroleum as taken from the wells contain from $\frac{1}{2}$ to 50 per cent of water in the form of small drops (i.e., emulsions), and after being allowed to stand for months still hold a great proportion of the water in suspension."

Judge Gilbert in his opinion says: "The specifications go on to say that the inventors had found that, when these emulsions are subjected to the action of high potential electric charges in the manner thereafter described, they are rapidly de-mulsified, the water settling to the bottom of the vessel, collecting into large masses, which can be readily withdrawn, leaving the oil dry.

"The process involved in the invention, as shown by the specifications, is substantially this: Oil loaded with water in the form of minute globules is passed between two electrodes separated at a proper distance, the electrodes being connected to a source of electricity of sufficiently high potential to create between the electrodes an electrostatic field or field of electric strain, which will cause the minute globules of water to conglomerate and coalesce until they become so large that they will settle out from the oil by gravity. For present purposes it is sufficient to quote the first claim:

"The improvement in the art of separating and collecting particles of one liquid suspended in another, which latter is essentially a non-conductor of electricity, consisting in bringing the material to be treated between electrodes connected to a source of electricity of sufficient voltage to produce coalescence of the suspended particles in such wise as to cause the rapid separation of the two liquids throughout the body of the mixture, and at the same time prevent the coalescing globules from forming complete chains, short-circuiting the electrodes."

CONTENTION OF THE APPELLEE

"The appellee (Reward Oil Co.), operating under a patent issued Oct. 26, 1915, No. 1,158,253, for 'Process of Dehydrating Oil,' removes the moisture from oil by

passing the oil between electrodes connected to a source of electricity of sufficient voltage to cause the suspended particles to coalesce in such wise as to produce rapid separation of the two liquids throughout the body of the mixture. But the appellee contends that it does not infringe the appellant's (Petroleum Rectifying Co.) patent for the reason that it does not prevent the coalescing globules from 'forming complete chains, short-circuiting the electrodes.' Therein is the whole ground of controversy in the present suit. In both processes there are the electrodes, the sufficiently high voltage to produce coalescence of the moisture, and to separate the same from the oil. The only question is whether the operation involves different methods of electrical action. In the application for the McNear and Bowles patent reference was made to the appellant's patent as follows:

"Said patentees (Cottrell and Speed) relied upon the electromotive force only to break down the oil partitions between the water globules, and took especial pains to prevent short-circuiting between the electrodes, and, indeed, their inventions consisted wholly in the prevention of short-circuiting. We have discovered that far better results are obtained by relying, not upon electromotive force, but upon heat as an agent to produce coalescence between the water globules, this heat being produced by the passage of the very large electric current which is produced by short-circuiting, the amount of heat being such as to convert water globules in the path of the current into steam, and by said conversion breaking the electric current in said path."

"This fanciful explanation of the effect of the current in the appellee's process may be pardoned in view of the fact that neither the patentees of that patent nor any expert witness was able to say just what does occur in the mass of the fluid when under treatment in either process. The theory that in the appellee's process the water globules are by the electric current converted into steam is not established by evidence, and is discredited by the appellee's expert witnesses. The defense of non-infringement, therefore, rests upon the appellee's contention that in the appellant's process there is no passage of electric current from one electrode to another, and that the dehydration of oil accomplished therein is the result of the maintenance of an electrostatic condition in the fluid between the two electrodes, whereas in the appellee's process the dehydration is accomplished by the passage of currents of electricity from one electrode to another. In other words, according to the appellee, it is essential to the appellant's process that short-circuiting be avoided, while it is essential to the appellee's process that short-circuiting be produced. We are led, therefore, to the inquiry what is short-circuiting as referred to in the appellant's claims, and what is the proper construction of the appellant's claim where it provides for a source of electricity of sufficient voltage to prevent the coalescing globules from forming complete chains short-circuiting the electrodes."

CONCLUSIONS OF THE COURT

In concluding this inquiry the court says:

"The term 'short-circuiting' in the appellant's claims, if susceptible of two meanings, should be given that which the specifications show it was intended to have, if that meaning is not repugnant to the plain and clear terms used. Cottrell and Speed were the first to discover the process of dehydrating oil by electricity. Their invention went into large and extensive use. For

a time it was used by the appellee under a license. Prof. Cory states that so far as he knows it is a pioneer invention. It should receive a fairly liberal construction that will uphold rather than destroy. The construction given the term 'short-circuiting' by the court below is, we think, erroneous. What the inventors meant by the term was a total short-circuiting, and not the succession of minute short-circuits snapping from one electrode to another, whereby dehydration is accomplished in both the appellant's and the appellee's process. The claims of the appellant's patent must be read in the light of the invention as disclosed in the specifications. It appears therefrom that the inventors recognized the essential value of the formation of chains between the electrodes and the instantaneous disruption of the chains by electric current, and at the same time the necessity of maintaining the potentiality of the main current, and that it was to express that necessity that they inserted in the claims the caution against such short-circuiting of the current as to interfere with the process. They realized that the momentary passage of short currents between the electrodes would not 'short-circuit' their current in the sense in which they used that term in their claims."

Further the court said that it was not essential that patentees should either understand or set forth the scientific principle on which the patented process operated. It quoted from another decision where that court said:

"It may be that the inventor did not know what the scientific principle was or that knowing it, he omitted, from accident or design, to set it forth. That does not vitiate the patent. He sets forth the process or mode of operation which ends in the result, and the means for working out the process or mode of operation."

OPINION OF EXPERT WITNESS—VIEWS OF THE COURT

Prof. Cory, expert witness for the appellee, was of the opinion that chains were formed in appellant's process, the theory of which, as stated by the court, is that, if the voltage is sufficiently high, chains are formed and a current flow instantaneously occurs, which demolishes the chains, whereby the flow is arrested. That a variation in the current does occur in practice is shown in appellant's specifications, which state that when the proper electromotive force is applied the ammeter will show "irregular variation" in the current, or "occasional momentary variation."

Further, the appellee contended that the extensive use and great utility of appellant's process is owing to the use of the rotating type of treater disclosed in the Cottrell and Wright patent assigned appellant, and not involved in the present suit, and that the inventions disclosed in the patents in suit are not operative.

This contention the court held to be not sustained by the record. In the first, said the court, the fate of appellant's process patent is not linked with that of its apparatus patent. "No process patent is in theory either helped or harmed by the excellence or worthlessness of the disclosed apparatus by which it is illustrated." (255 Fed., 83.) In the instant case the court said: "Again, the evidence shows that it is not true that the first apparatus was a failure. A 'treater' constructed under the apparatus patent in 1909 was in use for several years. The evidence is that it required readjustment, and that it was not perfect in operation, and that some three years later the appellant resorted

to the use of treaters with revolving electrodes as disclosed in the Cottrell and Wright patent, and thereby increased the efficiency of the process from 15 to 25 per cent. No defects in the process patent, therefore, can be predicted upon defects in the apparatus patent, and the fact that the first apparatus was defective is no reason for denying protection to either the patented process or the apparatus. . . . If, as we have found, the appellee uses the appellant's process it is immaterial that by improvements in structure of its apparatus, the appellee has so increased the efficiency of its machine that it marks a distinct improvement upon the appellant's apparatus."

Purchaser Should Use Good Faith in Making Resale of Goods Not Up to Specifications

Judgment for Smith, DeMacedo & Co., Inc., Philadelphia, against Swift & Co. was recently affirmed by the Supreme Court of Pennsylvania. Swift & Co. had sold to the former company thirty-four tons of oleostearine, an article represented to be suitable for the same uses and to comply with the specifications set forth for stearic acid. It was to be resold and shipped for use in Portugal. Upon arrival there it was found the commodity did not conform to the specifications, and the customer declined to accept the shipment.

With concurrence of Swift & Co. the shipment was directed to be sold for the best price obtainable. Thereupon, the court said, it became the duty of Smith, DeMacedo & Co., Inc., through its agent, to exercise good faith, reasonable judgment and diligence in making a resale. If this were not done and the first seller sustained a loss thereby, the buyer cannot enforce the rule that the damages would be the difference between the value of the goods at the time of delivery and the value they would have had if they had answered the warranty (specification set forth on order) at the time and place of delivery.

There was evidence to show that a resale was necessary, and that owing to the lack of shipping facilities, the article could not be sold elsewhere than in Lisbon. The law is that in such cases the loss must be minimized by the holder of the goods and he will be held responsible for any negligence in reducing loss to the product.

Evidence as to the price obtained on the resale, introduced to show the measure of damages, such damages to the brokers being the difference between the contract price and the market price of the product, was objected to on the ground that the witness testifying knew nothing of market conditions. But the court said the sale took place through an experienced broker for the very best price obtainable, and it was not shown that such sale lacked good faith, nor that the circumstances under which the sale was made were calculated to produce the best price obtainable or to procure the best market price, nor for the reason that the evidence was but the opinion of the witness, nor because it did not appear that Smith, DeMacedo & Co. used reasonable efforts to secure the best obtainable price.

That the witness had no knowledge of the market condition was not availing since the price obtained through a fair sale would establish a market condition for that sale, and certainly would be the best price obtainable as agreed upon by the parties in ordering the resale. Of course, when such sale is unfair and damage results because the sale is below the market price, this latter price becomes important in establishing the seller's loss. Judgment for the brokerage company was affirmed.

Cure of Flakes by Proper Heat Treatment

An Account of a Heat-Treatment Practice Evolved for Heavy Nickel Steel Forgings Which Reduced Flaky Test Bars to 15 Per Cent of the Total, Based on the Idea That Most Flakes Are Caused by Internal Strains in the Metal

By C. S. CROUSE*

THINKING that the problems met and solved in evolving a standard practice in one plant might possibly prove of assistance to others, I have outlined the following observations which were taken over a period of about eight months and cover the time from the start of treating, through the experimentation period, up to and including the time when a standard practice was developed.

FURNACE EQUIPMENT

The heat-treating plant under observation was equipped with seven vertical, electric resistance type furnaces furnished by the General Electric Co., each one having six rows of nichrome heating elements or ribbons, the upper three and the lower three rows acting as independent units. Power was furnished by a three-phase, 220-volt alternating current. The furnaces (shown in Fig. 1) were cylindrical in shape, being made of fire-brick with a boiler plate shell, and a capacity of nine type A or eight type B forgings, which types will be explained below. The forgings were hung in a circle from a supporting spider (Fig. 2) so that their outer sides were within a few inches of the heating ribbons. Attached to the spider, by means of a heavy round bar, was an eye so that the whole charge might be handled as a unit by means of an overhead crane.

The charge and spider were in turn supported in the furnace by being suspended, by means of a square, flat plate under the eye, from two movable eye-beams which in turn rested on rails on either side of the furnace pit (see Fig. 1). After the charge was placed in the furnace the top was closed by rolling two semi-circular covers into place, these covers being made of brick incased in a casting. After the covers were closed there was very little loss of heat by radiation, thus making for a high heat efficiency.

The furnaces were further equipped with an automatic

FIG. 1. ELECTRIC RESISTANCE-TYPE FURNACE, COVERS ROLLED BACK. LOOKING DOWN

temperature control furnished by the Leeds & Northrup Co., which operated as follows: There were twelve holes in the sides of the furnace arranged in three rows spaced at thirds around the circumference, the holes in each row being spaced about equally from top to bottom of the furnace. These holes were for the purpose of inserting iron-constantan thermocouples through the wall of the furnace to actual contact with

FIG. 2. SKETCH OF FORGINGS SUPPORTING SPIDER

the forgings, all the holes, however, not being in use at any one time. There were also two other holes so situated that a couple might be inserted to get the nichrome ribbon temperature, one couple getting the temperature of the upper three rows of ribbons and the other that of the lower three rows.

Each half of the furnace was furnished with a recording pyrometer which plotted both the ribbon and the forging temperature in that part of the furnace and, being set for any temperature, automatically threw the current off and on so as to maintain that temperature. In addition there were extra thermocouples placed in each furnace and connected to a Leeds & Northrup multiple point recorder, this arrangement acting as a check on the other.

All cold junctions were carried up to the instruments in the pyrometer room, where they were automatically compensated. In addition, all couples and instruments

FIG. 3. FURNACE ROOM

Left, furnace pit; center, quenching tanks; right, cooling pit.

were carefully checked and standardized at frequent, stated intervals.

In addition to the furnaces, there were four cooling pits similar in design to the furnaces, but having no provision for heating. There were also two quenching tanks, one for water and the other for oil. However, after the first few weeks of treatment the oil, which was Robisoil No. 2, specific gravity 0.865, flash point 395, viscosity 140, was supplanted by water. In order to keep this cool, it was pumped out of the building, sprayed and returned to the tank. A general view of the whole department is given in Fig. 3.

FORGINGS TO BE TREATED

There were but two main classes of forgings treated, one of which will be called class A and the other class B, as shown in Fig. 4, the latter having the greater cross-sectional area, but being shorter. Both classes, however, varied in cross-section within themselves—that is, there was a certain cross-sectional area down to a shoulder and then a certain greater area below the shoulder.

Class A forgings were 9½ ft. long, the small section extending for 3 ft. 9 in. to a shoulder. The overall diameter at the small end was 6 in. and the diameter of the bore 2½ in., leaving a wall thickness of 1¾ in., while the overall diameter at the large end was 6½ in., with a bore diameter the same as the other end, leaving a wall thickness of 2¼ in. The first 6 in. of the smaller end, which was the waste or test metal, was slightly larger than the balance, thus leaving a slight shoulder under which clamps were placed and the forging thus attached to the spider. The approximate weight of the forging was 780 lb.

Class B forgings were 4 ft. long, the small section extending for 2 ft. 8 in. to a shoulder. The overall dimension at the smaller end was 9 in., and the diameter of the bore 5½ in., leaving a wall thickness of 1¾ in. The larger end was quite irregular, but averaged about 11½ in. for an outer diameter, while the bore diameter was 7 in., leaving a wall thickness of 2¼ in. This forging was suspended from rods thrust through holes bored in the 6 in. of test metal at the smaller end, as there was no shoulder at this end. The bore at the shoulder contracted to about 2½ in. in diameter for about ½ in. of length, making a heavy section at this point. The approximate weight of the forging was 407 lb.

Operations were started on 3 per cent nickel steel forgings (although a few contained some chromium as well as nickel), the carbon averaging around 0.38 per cent. The forgings were received direct from the forge plant with nothing done to them aside from a green

anneal to relieve the forging strains. After receipt at the plant they were rough machined and bored, then heat treated and tested, then finish machined, bored and assembled.

CARELESS ORIGINAL PRACTICE

The initial heat-treating practice was to place the forgings in a furnace entirely disregarding its temperature and without making any attempts to segregate the forgings in a charge with respect to their carbon content. The temperature of the furnace at this time, prior to the introduction of the forgings, averaged around 1,225 deg. F. (660 deg. C.). The charge was then brought to a temperature which averaged 1,425 or 1,525 deg. F. (775 or 830 deg. C.), depending on whether the forgings were to be quenched in water or in oil, in a length of time that averaged 3½ hr., when it was quenched in either water or oil, the medium chosen depending on the uniformity or lack of uniformity of the cross-sectional area of the forging, the one of uniform cross-sectional area being quenched in water and the one of irregular cross-section in oil. The object of this was, of course, to avoid cooling one part faster than another and so prevent strains from being set up that might crack the forging.

The temperature of the water before quenching was between 80 and 90 deg. F. (30 deg. C.) and the time of immersion averaged around 2 min. The temperature of the oil was a variable depending on how frequently it was used, as there was no provision made for cooling it. The time of immersion varied somewhat with the temperature of the oil, but for the same temperature it was always several times the period of immersion when water was used.

After quenching, the forgings were immediately put back into a furnace for the draw, its temperature averaging around 1,000 deg. F. (540 deg. C.) before the forgings were placed in it. The charge was then raised to a heat of between 1,100 and 1,200 deg. F. (620 deg. C.) and held at that temperature for about 1½ hr., the time of raising to heat being about 2½ hr.

In all cases the time that it took to raise a charge to heat varied with conditions and the time of holding at heat was regulated by the necessity of having each forging heated entirely through at the particular temperature desired. Also the operator had to be sure that sufficient time was given for the necessary changes to take place in the steel after the critical range had been passed, these changes being somewhat slowed up by the presence of the nickel.

After the draw was complete the charge was removed to a cold pit and allowed to cool to below 600 deg. F. (315 deg. C.) with the pit covers closed. This was for the purpose of protecting the forgings from air currents which might cause unequal cooling, setting up strains in the steel and causing warping and cracking.

As previously stated, there was about 6 in. of waste metal left on each end of both classes of forgings for

FIG. 4. SIZES OF NICKEL-STEEL FORGINGS TREATED

the purpose of furnishing test metal. After heat treatment, transverse bars were cut from this waste metal, one from each end, the bar from one end being diagonally opposite from the bar on the other. These bars were then shaped in shapers and turned down in lathes to the standard test bar 0.505 in. diameter, 2 in. between prick points. There were batteries of saws, drills, shapers and lathes kept for this purpose only. The bars were then pulled on one of three Riehle testing machines and the data carefully recorded and the fractured test pieces saved. The shapers, lathes and testing machines were run by girls under the supervision of men and, after a short period of training, they became very proficient.

After a considerable number of forgings had been tested, it was found that while some of them passed specifications there was no uniformity of result and something would have to be done to improve the percentage of acceptable pieces. The fractured test bars also showed a large number of flakes, of which I will say more later.

SEGREGATION ACCORDING TO COMPOSITION

A careful study of the results indicated that each heat-treatment charge should be made up of forgings with similar carbon content, within limits, and the heat treatment, especially the drawing temperature, regulated accordingly.

This was then done and the treatment changed so that the quenching temperature averaged about the same as before, but with the drawing temperatures ranging as low as 970 deg. F. (520 deg. C.). The time of holding at heat in the draw was also lengthened to 6 hr., though subsequently it was found that while this long time did no harm neither did it apparently do any good, so for the sake of economy it was materially reduced.

This practice increased the percentage of passed forgings to some extent, as was expected, but flakes and streaks still continued to appear in the fractured test bars.

DESCRIPTION OF OBSERVED FLAKES

Before going any further I will define "flake" and "streak" as they occurred in the transverse test bars. A flake is apparent to the eye as a spot of any size occurring in the fractured surface of the test specimen and extending transversely across it, the plane of the flake being parallel to the long axis of the forging. A streak is a bright band, generally about 0.02 in. (0.5 mm.) in width, apparently of the same nature as a flake, but having the plane of the defect at right angles to the long axis of the forging. In other words, when testing transversely a "streak" is a flake parallel to the axis of the test piece, a "flake" is perpendicular to it.

FLAKES ASCRIBED TO STRAINS IN STEEL

A cause for the existence of these flakes and streaks was then sought, and it was generally agreed that they were due to strains in the steel, but whether they were in the steel before heat treatment, whether heat treatment caused them, or whether, if they were present before treatment, the treatment could eliminate them was not plain. Accordingly a careful study of the treatment was made to see if undue strains were being set up in the forgings by the practice being followed at that time, and it was decided that the habit of putting a cold forging in a hot furnace was very apt to set up

strains in the steel and that even though these strains were not sufficient to cause flakes the practice was not a good one and should be eliminated. In this connection the following test was made. One end of a small metal rod, on the other end of which was a telephone receiver, was thrust through a thermocouple hole in the side of a furnace and up against a forging. By listening at the receiver a person could hear what seemed to be straining or cracking noises when the forging was heated rapidly and this apparently indicated a rather severe straining of the metal under the given conditions. However, this experiment could not be taken as conclusive, as the intensity of the sounds, and even the very existence of them at all, varied with the listener.

However, in view of the above findings, the experiment was tried of putting the forgings into a cold furnace and bringing them to heat very slowly, the time varying from 16 to 20 hr. and, at times, even longer. This practice was tried for about 10 days, but only as an experiment, being diametrically opposite to the previous practice of putting the forgings in a hot furnace and bringing them to heat as rapidly as possible. Ten days was found to be sufficient to get enough data on which to base conclusions.

Of course the extreme length of time involved in bringing the charge to heat precluded the adoption of this method commercially, but the results obtained showed that it was a step, though a radical one, in the right direction. However, flakes and streaks still persisted, and it was decided that they must be formed prior to forging, which the writer had contended right along, and experiments were accordingly undertaken with that idea as a basis.

FLAKES FOUND IN INGOTS

As previously stated, the steel was made and forged at another plant than where treatment and machining were done. The casting practice at that time was to cast into square ingots and cool in the air. Experiments were begun at the beginning of things, therefore, and a number of these square ingots were cut open. It was found that flakes appeared along the diagonal lines across the ingot from corner to corner. As the corners or edges of a square ingot cool first, thus setting up strains along these same diagonal lines, it was deduced that flakes were caused, in part at least, by cooling strains and experimentation proceeded accordingly.

The shape of the ingots was changed from square to octagonal and the hot ingots were stripped and buried in ashes to cool, thus insuring very slow and uniform cooling. A number of these ingots were then cut open and flakes were found to have been practically eliminated. This casting and cooling practice was accordingly followed from then on, with such modifications as conditions from time to time indicated, and very little further trouble was experienced with flakes.

This all proved that while the initial heat-treatment practice was not all that it might have been, still the low percentage of passed forgings was due as much to poor steel as it was to poor heat treatment.

As stated before, the long time required to bring a forging to heat when put in a cold furnace and raised very slowly precluded the use of this practice commercially, so the following scheme was evolved which worked out very well.

It is generally agreed, I believe, that if the difference in temperature between the furnace and the forgings

is not more than 300 to 400 deg. F. (175 deg. C.) no undue strains will be set up in the steel and also that after the forgings are raised to a temperature of between 600 to 700 deg. F. (340 deg. C.) even a greater difference in temperature will do no harm. Working on these premises, one furnace was set aside for a pre-heating furnace, the cold charge being placed therein when the furnace temperature was around 400 deg. F. The charge was then brought up to about 700 deg. F., when it was removed to another furnace which was at a considerably higher temperature and there brought to heat. The temperature of this second furnace before receiving the charge varied from 1,000 to 1,200 deg. F. (600 deg. C.) depending on circumstances. As far as the draw was concerned, the forgings were removed from the quenching bath at a sufficiently high temperature so that they could be put into a furnace at a relatively high temperature without any harm ensuing.

The foregoing improvements in both steel and treating practice resulted in a material increase in forgings passed, but the percentage was not yet what it should have been and a study was made of the quenching and drawing temperatures to see what improvements could be inaugurated along those lines.

At this time 3 per cent and 2 per cent nickel-steel and 3 per cent nickel-chromium steels were being treated, and it was found that the quenching temperatures could

FIG. 5. RELATION BETWEEN PHYSICAL PROPERTIES AND DRAWING TEMPERATURES IN THE HEAT TREATMENT OF LARGE NICKEL-STEEL FORGINGS

be practically standardized for all three classes if the drawing temperatures were properly adjusted. The following practice was accordingly evolved, which resulted in passing about 85 per cent of the forgings on the first treatment.

The forgings were placed in a furnace which was at a temperature of from 500 to 700 deg. F. (315 deg. C.), heated through to this temperature, and then transferred to another furnace which was at a higher temperature, as explained before. In this second furnace class A forgings were raised to a heat of 1,475 deg. F. (802 deg. C.) and class B forgings to 1,500 deg. F. (816 deg. C.) in a time of from 8 to 12 hr. They were then held at heat for a time of 1 1/2 hr. for class A and 2 hr. for class B forgings and quenched in water.

For class A forgings the time of total immersion was 1 1/2 min., at the expiration of which time the forgings

were pulled up till the shoulder was just beneath the surface of the water, when the heavy section was given an additional quench of 30 sec. In the case of class B forgings the time of immersion of the whole forging was 1 min., with an additional minute for the heavy section. These quenching times were found to be adequate for getting the proper quenching effect and yet did not cool the forgings so low as to cause cracks, which danger is always present in alloy steels. Neither did the forgings lose an unnecessary amount of heat, thus causing the necessity for more power consumption and a needlessly long time for bringing the charge to heat in the draw.

After the quench the charge was put back into the drawing furnace, whose temperature varied from 900 to 1,050 deg. F. (525 deg. C.) and raised to heat in from 2 to 4 hr. It was held at heat for 3 hr., removed to a closed pit and cooled to below 600 deg. F. (315 deg. C.) with the pit covers closed.

As stated before, the practice outlined above resulted in the passing of about 85 per cent of the forgings on the first treatment and was followed, with perhaps minor modifications for varying conditions, from the time it was evolved till the plant closed.

The accompanying chart, Fig. 5, shows the relation between the drawing temperatures and the carbon content of the steel for the three classes of material used, the forgings in all charges used in preparing the chart having passed test on the physical properties shown.

In conclusion the writer wishes to state that the above article was written before the recent rather general discussion in the technical press on flakes in nickel-steel forgings and he wishes to be understood as advancing no theories, but as merely stating facts, leaving the reader to draw his own inferences.

Lexington, Ky.

Conserving Canada's Pulp-Wood Resources

Canada produces something like 800,000 tons of paper per annum, and after supplying its own needs finds a ready market in the United States for the greater part of the remainder. The Dominion is making rapid progress with the development of its wood-pulp industry, the output of which, according to the latest available official figures, rose from 363,079 tons in 1908 to 1,464,308 tons in 1917.

Its illimitable virgin forest areas and its policy of conservation and reforestation should in the near future make Canada one of the greatest pulp and paper producing countries in the world, but today it cannot meet anything like the demand for either commodity from the United States—which normally takes 75 per cent of Canada's output of paper—or from Great Britain, Australia, New Zealand, and South Africa. The provincial governments of Canada, in refusing to permit the export of pulp wood grown on Crown lands, are naturally unwilling to exploit their forests without regard to conservation, but are perfectly willing to continue to send to the United States most of their output of print paper.

It is extremely doubtful whether the paper consumer—large or small—will experience much relief in respect of prices within the next two or three years. While wood pulp continues to be the principal raw material for paper, conservation of the world's pulp wood areas should certainly be supplemented by a thorough investigation of the adaptability of other fibers to paper-making purposes.

The Chemical Engineer—His Functions and Training*

An English View of the Functions of Three Classes of Chemical Engineers: Those Employed in Chemical Works, Those Engaged in Manufacturing Chemical Plant, and Consultants—Suggested Curricula for Students Who Have Had Preliminary Training in Chemistry or Engineering

By J. H. WEST

MUCH has been written at various times on this subject, and it is one of peculiar importance just now in view of the great and increasing interest which is being taken in the provision of adequate facilities for the training of chemical engineers in this country [England]. It is, however, evident that there is still much confusion of thought as to the proper functions of a chemical engineer, and until this matter is cleared up there can be no real progress in devising the correct lines upon which his training should be carried out. The recent very interesting informal discussion on "What Is a Chemical Engineer?" at the Chemical Industry Club provided a further proof of this confusion of thought, some speakers even going so far as to consider a chemical engineer as a sort of super-plant-superintendent.

The object of this article is to analyze the functions of chemical engineers in relation to chemical manufacture, to classify these functions into their various groups, and then to discuss the various sources from which the chemical engineers of the future are likely to come, thereby arriving at the nature of the training they will have had previous to entering upon the study of chemical engineering proper, and finally to offer some suggestions as to the training they will require, and how this is to be provided. The writer does not desire in any sense to lay down the law on these matters, but rather to open the way for an unbiased consideration of this subject, which is of the highest importance to the whole British chemical industry, based upon clear thinking and a practical appreciation of the actual conditions under which chemical manufacture is being carried out to-day.

The report of the British mission which investigated the German chemical factories in the occupied territory makes it clear that Germany's past supremacy in the chemical industry was not due to superior and exclusive knowledge on the part of her chemists, but rather to highly organized and well-thought-out methods of manufacture carried out in scientifically designed plants. There is still, unfortunately, a certain amount of apathy among British chemical manufacturers regarding these questions, though not nearly as much as before the war, some of the older concerns attaching far more importance to guarding the secrets of their old-time methods than to keeping in touch with new methods and new discoveries. Others, however, realize even now that a bitter fight for commercial existence may soon be upon them, and they are making their plans accordingly. It is essentially the chemical manufacturer who is chiefly interested in obtaining and utilizing competent chemical engineers, and any criticisms or suggestions regarding the points referred to in this article will be most heartily welcomed from chemical manufacturers,

and also from others who are interested in the training of chemical engineers.

Functions of the Chemical Engineer

Chemical engineers may be divided into three main classes. First, those who are employed in chemical works; second, those who are engaged in manufacturing chemical plant; and, lastly, consultants. These three classes will be dealt with in turn.

THE CHEMICAL ENGINEER IN A LARGE WORKS

In order to arrive at a clear understanding of the functions of a chemical engineer engaged in a chemical works it is necessary first to consider his duties in a large works where the organization is highly developed with a large staff, and consequently there is less overlapping of duties than is inevitable in a small works with a correspondingly small staff, because such overlapping tends to obscure his true functions. These duties were fully gone into by the present writer in a previous article¹ and it is not, therefore, necessary to go all over the ground again, but there are certain points which must be emphasized, and in order to make them clear it is here necessary to make a digression.

PHASES OF CHEMICAL MANUFACTURE

The principal point, in the writer's opinion, is that there are, and must be, three distinct sides or aspects of chemical manufacture, leaving aside financial and selling considerations. These are the chemical side, the manufacturing or production side, and the engineering side. The second is by far the most important, for it is obviously the main business of the works, and the two others are merely adjuncts necessary in order that the production side can be carried on. It is becoming more and more realized by progressive manufacturers that production is a science in itself, which should be kept separate from other phases of the work and placed in the hands of trained production experts. In any manufacturing industry, whether gas-engines, boots, chemicals or anything else is being made, the production man is given certain materials to transform into certain products, and he is provided with the necessary means of doing this—viz., first, what may be termed plans of operation, for lack of a better term; second, plant; third, labor; fourth, energy; and lastly, subsidiary materials, other than raw materials.

Take the case of a works making gas-engines. The raw materials are pig iron, ingot metals for non-ferrous alloys, bar and sheet metals, and various sundries. The plans of operation consist of the designs for the gas engines prepared by the designing and drawing office staff, and the methods of manufacture which are worked out partly by the drawing office and

*Reprinted from the *Chemical Trade Journal and Chemical Engineer*, June 5, 1920, p. 727.

¹"The Manufacturing Organization of Large Works," *Chem. Trade J.*, Feb. 9, 1918.

partly by the tool-room staff. The modern tendency is all toward working out the various processes of foundry work, machining and assembling beforehand by the joint drawing office and tool-room staffs, so that the production man gets all these matters cut and dried, and has not got to work them out for himself.

The case of chemical manufacture is almost exactly parallel. The raw materials depend upon the products to be made. The plans of operation are the chemical processes as worked out by the chemical staff, and the methods of carrying out the various chemical and physical operations as worked out by the chemical engineering staff. Here, again, the production man should be provided with all his requirements without having to bother himself about them, so that he can devote his whole time and energy to his own job, that of production. Now, production is not chemical work, and it is not engineering. It is a thing apart, calling for special knowledge of organization, the handling of labor and materials, the saving of time, and the economics of manufacture, as well as some knowledge of chemistry and engineering. There are many people who believe that a chemical plant can be run successfully only by a chemist. If that is true in the case of a given plant or process it is a sure sign that either the process has not been fully worked out by the research chemist, or that the plant and methods of operating have not been properly worked out by the chemical engineer. When a chemist says that he must run a process himself it simply means that he has turned over an incomplete process to the works and that he will complete his research on the plant itself. Now, a manufacturing plant is not the proper place for research if it can possibly be avoided, because research in such a plant inevitably means interference with production.

In the case of large firms with a well equipped semi-manufacturing scale laboratory practically every point regarding both process and plant can be worked out there, but smaller firms regard these laboratories as luxuries beyond their means, though in reality they would in most cases recoup the entire cost of such a laboratory within a year by the saving in time and money on their manufacturing plants. However, if there is no such laboratory the final stages of the process and plant research must be carried out in the manufacturing plant; but this should be placed under the control of the production man from the outset, with the chemist and chemical engineer to assist him until the initial difficulties have been overcome and the production is working smoothly. When this stage is reached the investigation of the process and plant and the methods of working should be so complete that the whole thing is practically foolproof. The production man should then, and then only, take full charge, leaving the chemist and the chemical engineer free to tackle other problems, and only needing to be recalled to give advice if and when other difficulties arise.

PRODUCTION WORK NOT REAL CHEMICAL WORK

Once the production is going smoothly by no stretch of the imagination can it be claimed that there is any real chemical work, in the highest sense of the words, involved in carrying it on. There will be routine testing of raw materials and reagents, and of the products at various stages of manufacture, including the finished article, but once these tests have been worked out and systematized a chemical student straight from college could carry them out, and how any chemist who is a real

chemist can wish to have anything more to do with the plant when there is other research work—real chemical work—waiting to be done is a mystery, except that many chemists seem to prefer any sort of work almost to chemical work. There is no reason why a man who has been trained as a chemist should not take up production work in a chemical factory, provided he acquires the necessary knowledge of the science of production, and his chemical knowledge will be very useful to him; but he should frankly acknowledge when he does so that he has changed his vocation and is no longer doing the work of a chemist. The same thing applies to a chemical engineer who desires to run his plants when they are completed. Let him do so, if he has the necessary knowledge and ability, but let him also realize that by so doing he has ceased to work as a chemical engineer.

DUTIES OF CHEMICAL ENGINEER

True chemical engineering is a branch of engineering, just as much as electrical engineering or mining engineering, and it is nothing else. The real chemical engineer must be an engineer first, last and all the time, and his original training must be an engineering training, including the serving of an apprenticeship in the shops, as in the case of any other true engineer. To this must be added a real aptitude for and knowledge of chemistry, physics, and physical chemistry, particularly the two latter. It is primarily a man with such a training followed by sufficient practical experience who will be best fitted for carrying out the design and construction of original and complicated chemical plant without outside assistance. This work is the principal function of the chemical engineer, but he must be prepared, in addition, to assist and advise the various experts in other branches of engineering, such as power and steam engineers, structural engineers and electrical engineers, who will be on the staff of a large chemical works, or who may be called in from outside, regarding the special requirements of chemical works in these directions. He must, further, in order to fulfill these functions, collaborate closely with the chemical staff, the production staff, and the other engineering experts, including the repairs engineer, and he will have to deal with outside makers of plant, and select the most suitable types, arranging for any modifications of the makers' standards, if such be absolutely necessary.

PUTTING A PROCESS ON A COMMERCIAL SCALE

The ideal method for preparing a laboratory chemical process for conversion into a manufacturing proposition would be a joint investigation carried out in the closest collaboration by the chemist, the production man and the chemical engineer, bearing in mind that the production man, as representing the commercial point of view, is the most important. The chemist would therefore have to satisfy him that the process he submitted involved no waste of materials by the use of excess reagents beyond that absolutely necessary to carry out the reactions, that expensive reagents were not to be used where cheaper ones would do, that the yields had been pushed to the highest point attainable, and that the use of power and heat had been reduced to a minimum. The chemical engineer would have to satisfy him that the plant proposed was in every way suitable and efficient, and that economy of labor, power, heat, cooling water, etc., had been fully provided for. By the production man is here meant the head man or production superintendent of the whole works. The man who

is to run the plant should be brought into touch with it during the construction period, so that he will be familiar with every detail of the plant and process before he has to begin operations. A board of directors who insisted upon the preparations for manufacturing their products being carried out in this way would feel confident that not only were they using their staff to the best advantage but were insuring commercial success as far as that can possibly be done.

THE CHEMICAL ENGINEER IN A SMALL WORKS

So much for the works chemical engineer in a large works where his duties are highly specialized, and therefore clearly defined. We come next to the smaller works, where there is a chief chemist, with one or two research and routine chemists under him, and a chemical engineer. Here again, in the writer's considered opinion, far-seeing manufacturers who study organization and think out things for themselves will ultimately be driven to the conclusion that it is better to employ special production men to run the plants, and use the chemists and engineer to do their own proper work. In this case the methods of collaboration by chemist, production man and chemical engineer will be similar to those already considered, but if shift chemists are to run the plants the chief chemist alone will collaborate with the chemical engineer, and the onus of securing maximum economy of labor, power, heat, etc., will lie upon the latter. In either case the whole of the engineering work will have to be carried out by the chemical engineer, unless outside experts are called in, say, for instance, where a whole new works has to be laid out. It must be realized that the engineering problems connected with a chemical works cover such an enormously wide field that it is absolutely impossible for any one man to have expert knowledge of every phase, but, as before explained, the chemical engineer will assist these experts in satisfying the peculiar requirements of the chemical works.

WHERE THE CHEMIST IS ALSO THE CHEMICAL ENGINEER

Lastly we come to the all too common case of the works where there is a trained chemist but no chemical engineer, his place being taken by an engineering foreman as a rule, very often an ex-sea-going engineer who has picked up a practical knowledge of chemical plant, but has no knowledge of the principles of chemical engineering. This is a state of affairs which will probably cease to exist in a few years, when there is an adequate supply of trained chemical engineers, but it is very common at present, and it has led to the idea that if the chemist in such a case studies chemical engineering he can combine his own functions with those of the chemical engineer, thus becoming a sort of hybrid. That this is the sole conception of a chemical engineer possessed by many people was evident from the remarks of several speakers at the Chemical Industry Club debate, before alluded to. In fact, it was suggested that the name for this hybrid was badly chosen, and that it ought to be engineer-chemist. There is truth in this suggestion, for how can a man without a proper engineering training be an engineer? That a knowledge of chemical engineering, even of the most empirical kind, is most valuable to such a man is obvious, and that with the aid of outside engineers or chemical plant-makers he can do fairly good work in getting together plants in which to carry out his processes is not denied. There must be hundreds of chemical works in operation

today which have had every bit of plant in them got out and put up on these lines, but such a man is not a chemical engineer, or an engineer at all in the true sense.

RESEARCH SHOULD PRECEDE LARGE-SCALE PRODUCTION

It is most probable that here we come up against the fundamental difference between British and German methods. The British manufacturer is satisfied if his staff can get together and put up a plant which will turn out a given product, and as soon as the process has been decided upon the plant is got on with and production is begun, all question of commercial efficiency and most of the snags and difficulties of large-scale manufacture being left over until the plant is working. It is not too much to say that many chemical plants in this country remain in the experimental stage for several years after they start producing, and some plants seem never to emerge from this stage at all. The result is variable quantity and quality of output, with correspondingly disappointing financial returns, due to the occurrence of difficulties which ought to have been investigated and got over beforehand. The German manufacturer, on the other hand, insists upon every phase of both process and plant being worked out in advance by highly trained specialists. In other words, the research work is carried much further than is done here, where research is usually restricted to the purely chemical laboratory-scale stage, instead of being carried right up to the manufacturing stage, both as regards process and plant. Research on the chemical engineering and production sides is just as necessary as on the chemical side.

A well-equipped semi-manufacturing-scale laboratory is exceedingly useful for this work, but much can be done with odd pieces of spare or disused plant, and the proper use of the quantitative flow sheet, on which the history of every pound of raw materials, reagents and solvents, and every unit of heat and other forms of energy, from the moment they enter the plant to the moment they leave it, is worked out as closely as possible, will throw a flood of light on the extent and exactness of the knowledge of the process and the plant which has been acquired. With regard to the hybrid engineer-chemist, while it is admitted that he can devise, put up and run plants, can he possibly have sufficient specialized knowledge of the chemical, the engineering and the production sides to do full justice to all three? Heaven knows life is all too short for acquiring adequate knowledge and experience of one small corner of one branch of one department of technology, without attempting more than one.

THE CHEMICAL ENGINEER AS MAKER OF CHEMICAL PLANT

Passing next to the second class of chemical engineers, those employed by firms manufacturing chemical plant, the functions and qualifications will be very similar to those of the chemical engineer in a large chemical works. A less extended knowledge of chemical plant will be demanded, because he will only be required to deal with the special types of plant manufactured by his firm, but, on the other hand, he will have to study the application of these types to a much wider range of chemical manufactures than the works chemical engineer, who is confined to dealing with only one class of chemical products. This class of chemical engineer, again, must be a properly trained engineer, capable of

designing plant not only suitable for the purpose intended but capable of being manufactured on economical lines at competitive prices. Makers of chemical plant can be, and are, of immense assistance to chemical manufacturers, particularly those who have no chemical engineer of their own, and there are plenty of honest makers who are willing to give disinterested advice whether it results in the sale of their own plant or not. There are, unfortunately, others, happily in the minority, who are sufficiently blind to their own real interests to push the sale of their goods, irrespective of the suitability or otherwise of these for the purpose in view.

THE CONSULTING CHEMICAL ENGINEER

Finally, we have the consulting chemical engineer, who may have started life as a works chemical engineer or as a maker of chemical plant, and, provided he has had a thorough training and a sufficiently wide experience, it does not matter which. The proper functions of a consulting chemical engineer are to advise on the design and construction of chemical plant, the layout of chemical works, and, either alone, or in the case of large and important undertakings preferably in consultation with other experts, upon the other phases of chemical works engineering, such as buildings and the supply of steam and power. It is no part of his business to advise upon the purely chemical side of processes, any more than it is the legitimate business of consulting chemists to advise upon the design of chemical plant, yet consulting chemists frequently do the latter, sometimes with disastrous results, and consulting chemical engineers are often expected to do the former. Here again, in this age of specialization, overlapping of functions is greatly to be deprecated. In the consulting chemical engineer the chemical manufacturer who has no chemical engineer of his own can find an unbiased arbitrator between himself and the maker of chemical plant.

Training the Chemical Engineer

In considering the training of the chemical engineer it is necessary to differentiate carefully between the various classes of men who require training. Starting with the college student, it must be pointed out that at present, anyway, chemical engineering must be considered as more or less a post-graduate subject or as a subject to be taken up after the student has put in at least two years on either engineering or chemistry, consequently the training required will be very different in its early stages, according to the previous record of the student. The supply of students who begin with an engineering training, and later on take up chemical engineering, is likely to be small for some years, or until chemical engineering comes to be recognized as a well-defined and attractive branch of engineering, but it is probably men of this class, engineers at heart, with an aptitude for chemistry, who will make the best chemical engineers of the highest type. These men will have served their time in the shops, either before going to college or during their engineering course on the so-called sandwich system, and they will have had a thorough grounding in engineering subjects, so that they need not devote time to these subjects during their first year at chemical engineering. They should rather study as much chemical technology, physical chemistry, electrochemistry and thermodynamics as possible, plenty of laboratory work in all these subjects being

included, and one day per week being devoted to the principles of chemical engineering.

On the other hand, students with a chemical training should in their first year give three days a week to engineering subjects, including applied mechanics, strength of materials, machine drawing and design, and building construction, with one day on thermodynamics, physical chemistry and chemical technology, and the remaining day on chemical engineering principles. During the second year all students would devote most of the time to the principles of chemical engineering and the design of chemical plant, the remainder of the time being spent on chemical and physical subjects by the engineering students, and on engineering and physical subjects by the chemical students. The economics of chemical manufacture should also be dealt with, and such matters as the factory law relating to chemical works, safety appliances and the handling of labor. Students who can stay on for a third year would have advanced lectures on chemical engineering principles and practice, and would be encouraged to specialize in some branch of the subject in which they would carry out original investigations. The above is merely intended as a suggested general allocation of time.

PLANT EXPERIENCE ESSENTIAL

Works experience is most essential for all students, and is very difficult to provide for. If it can possibly be managed students should spend some months in a chemical works, or failing that in the works of a firm making a wide range of chemical plant. Possibly one summer vacation spent in each kind of works would be the best arrangement. It is greatly to be hoped that chemical manufacturers, when they begin to realize that properly trained chemical engineers will be not only valuable but essential to them, will come forward to aid the educational authorities by opening their works to students during the vacations. Chemical students who wish to acquire some knowledge of chemical engineering—and this subject is bound to be of great value to every chemist who intends to enter the chemical industry, whether on the research side or the plant side,—would take as much of the above course as they could spare time for.

CHEMICAL INDUSTRY SEEKS HIGHLY TRAINED MEN

In this connection it is worth referring to some remarks made by Dr. E. F. Armstrong, F.R.S., at the annual dinner of the Chemical Engineering Group, to the effect that the supply of partly trained chemists was likely greatly to exceed the demand, and that manufacturers now wanted not merely pass or honors degree men but highly trained chemists capable of undertaking the highest type of research work. Such men will certainly require a knowledge of chemical engineering. It might be added that there will no doubt be good openings for men with a chemical training who definitely propose to go in for plant or production work instead of research work, and prepare themselves for this by studying the economics of chemical manufacture, the principles of plant and works management, and chemical engineering; if necessary, abbreviating their purely chemical training in order to do this.

The training of production men lies outside the scope of this article, but it would appear that there is great need for a systematic course of training for plant superintendents and works managers, arranged on broad lines suitable to any manufacturing industry.

The Copper Industry in 1919

THE principal features of the American copper industry during the year 1919 are shown in an advance statement on the production of copper in the United States by H. A. C. Jenison, of the United States Geological Survey, Department of the Interior.

The smelter output in 1919 was about 1,310,972,000 lb., a decrease of 597,561,000 lb. from that of 1918. The production of refined primary and secondary copper from domestic and foreign ore and metal was 1,863,580,000 lb., which was 612,497,000 lb. less than the production in 1918. Refined primary copper amounting to 326,043,000 lb. was produced from ore or other material imported from foreign countries, principally Chile, Peru, Mexico and Canada.

The discrepancy between the smelter production and the refinery production is due to the fact that 562,000,000 lb. of blister copper and other material was in process of refining at smelters and refineries or in transit on Jan. 1, 1919, and though it was smelted in 1918 it was not refined until 1919.

EXPORTS SHOW GREAT FALLING OFF

In 1919 the imports of copper in all forms amounted to 429,388,000 lb., and the exports of copper in all forms amounted to 516,628,000 lb., which was 231,062,000 lb. less than the exports in 1918 and 616,205,000 lb. less than those in 1917. The exports in 1919 were less than in any year since 1907.

On Jan. 1, 1919, the stocks of refined copper were 180,000,000 lb., and on Jan. 1, 1920, they were 631,000,000 lb., an increase during 1919 of about 451,000,000 lb. The stocks on Jan. 1, 1920, were several times greater than they have ever been before.

In addition to the stocks of refined copper in hand about 310,000,000 lb. of blister copper and material was in process of refining at smelters and refineries or in transit on Jan. 1, 1920. This estimate does not include blister in foreign smelters destined for the United States for refining nor material in transit to the United States from such smelters.

The apparent domestic consumption in 1919 was about 876,564,000 lb., which is 785,106,000 lb. less than that in 1918 and less than the domestic consumption in any year since 1914.

CAUSES OF DECREASE IN OUTPUT

Many causes contributed to decrease the smelter and refinery production, the domestic consumption, and the exports, and to increase the stocks, but the principal cause was a poor market. The industry was working at maximum capacity when the war demand for copper ceased, and it was then, of course, forced to continue production only at the rate required to supply the ordinary commercial and industrial demand. The war demand was stopped so suddenly as to disturb greatly the trade and industrial conditions, and the prospects for the immediate future appeared so uncertain that few industries were able to continue production without first decreasing it greatly and reorganizing, to some extent, their industrial mechanism.

PRICES AND COSTS

Under the peace-time conditions the demand for copper was small and the average price soon fell from 24.7c. to about 15c. a lb. This price was far below the actual cost of the production of a very large part

of the previous year's output. All smelters and mines were forced to decrease production. Some were shut down entirely; others were operated at the minimum capacity that would keep the organization intact and the equipment in proper order. Much of the copper in stock could not be profitably held, and the placing of a large part of it on the market kept the price down, though it showed a tendency to rise when the readjustment set in.

PRICE LOWEST SINCE 1915

The price during the year showed many fluctuations but averaged only 18.6c. a lb., which was about 24 per cent less than the average price in any year since 1915, though the cost of labor and supplies had risen as much as 150 per cent during that time.

The labor troubles in other industries decreased the demand for copper, increased the cost of supplies used by the copper industry, and materially increased the cost of production.

DECREASE IN FOREIGN DEMAND

By the time the price of copper had risen high enough to permit the industry to meet these unfortunate conditions foreign exchange began to fall so rapidly that foreign buyers were unable or reluctant to purchase American copper, and finally the exchange between the United States and foreign centers dropped so low that they could no longer buy it. These conditions almost ruined the foreign market for American copper, and the demand and the price in the domestic market were less than they had been at any time for several years. On the whole, the year was an unsuccessful one, and in view of the conditions it is remarkable that the industry remained as stable as it did.

PROSPECTS FOR 1920

It is hard to foresee what improvement can be expected in 1920, but the quantity of copper sold in the early part of 1920 indicates that the year will be better than 1919. Any improvement, however, will be temporary and no stability or security can be found until existing troubles are settled and industry and trade become more stable. The prosperity of the copper industry is peculiarly dependent upon the establishment of stability in other industries, and before the industry can receive any great stimulus the condition of labor and of trade generally, not only in America but in Europe, must be greatly improved. When that time comes the industry will undoubtedly be as prosperous as ever.

Manganese Addition Increases Life of Thermit Welded Wabblers

Successful results obtained from a considerable number of welds made by several large steel mills have shown, according to a statement by the Metal & Thermit Corporation, New York City, that the life of wabblers on pinions, rolls and large shafts which have been repaired by thermit welding, after previously having been worn away or broken, can be prolonged materially by the addition of 3 per cent pure manganese to the railroad thermit in addition to the 1 per cent pure manganese already in the thermit. This will give a hard wearing surface. Wabblers should be thoroughly heated to about 1,400 deg. F. before welding; otherwise no alloying of the two metals will be obtained.

Turpentine From British Columbia Firs

IN A recent interview E. S. Oliver, an industrial chemist and specialist on wood products, who has made a study of methods of extracting the maximum amount of resin from trees without injury to the growing tree, gave some interesting and valuable information in connection with the turpentine industry, which is attracting considerable attention among persons identified with the development of the resources of British Columbia. Mr. Oliver, who has in the past conducted investigations in Mexico and Central America and in the forests of Russia, Sweden, Germany and the Mediterranean countries, states that the greatest potential source of turpentine and resin chemicals lies in British Columbia.

GOVERNMENT ISSUES "RESIN LEASES"

At the last session of the provincial legislature of British Columbia there was passed an amendment to the Forest Act, whereby the provincial government is authorized to issue "resin leases" and to collect a royalty of three-quarters of a cent a gallon on all resin gathered, in addition to the fees and rentals paid into the Forest Protection Fund. The amendment was passed only after demonstrations by, and reports from, forestry officials showing that tapping for resin does not injure the growing trees.

THE OLIVER METHOD OF COLLECTION

Some of the interesting history of this new industry was revealed when Mr. Oliver pointed out that the very first ship which came from England to the shores of America bore instructions, written in the hand of Queen Elizabeth herself, as to the method to be employed in securing tree resin. "And," he added, "curiously enough, on this continent the very same methods are still followed. It is an industry which has shown no improvement in its methods of collecting its raw material."

Under the old system of scarifying the barks of the trees and collecting the resin after the more volatile elements had become oxidized by contact with the air, it was not possible to secure more than 17½ per cent bulk of turpentine. In Canada the highest production in any of the eastern plants was 15½ per cent. Under Mr. Oliver's tests the lowest he has received was 33 per cent, or 1 per cent higher than in Germany, where the resin byproduct industry has been developed to an art.

PROCESS BENEFITS THE TREES

Without disclosing any of the secrets of the process, it may be said that Mr. Oliver achieves his results by boring a very small hole into the tree trunk and hermetically sealing it to an air-tight flask. In this way, instead of injury being done to the timber, the growth of the tree is aided. The resin being in the nature of fecal matter which the tree is seeking to rid itself of, the quality of the timber and the rapidity of its growth are aided, the small drain holes not affecting the efforts of the tree to send up sap and build up new cells.

MANY VALUABLE RESIN PRODUCTS

The theory worked out by Mr. Oliver to explain why larches and pines send out resin is that the pines and

conifers are the survivors of a cold epoch which swept over the northern hemisphere. The only way in which the germ of life in the tree cell could endure was by the tree evolving a non-freezable and non-swelling substance to enwrap and protect the cells. Such a substance is turpentine, which forms a large element in tree resin. "With a return of warmth," says Mr. Oliver, "these trees now find themselves with a supply of resin for which they no longer have any use. The tree is always seeking to rid itself of the substance by discharging through the roots into the ground and by forming abscesses in the tree trunk. When the tree trunk is scarified or the bark injured the resin oozes out."

Among the valuable products obtained as a result of experiments with British Columbia Douglas fir resins are turpentine, fir oils which form the base of "fruit" extracts used at soda fountains, medical oils, etc., and resins which make varnishes of the highest grade. Printing inks are also made from the resin. One of the most interesting is Burgundy pitch, which, instead of being "pitch" black, is snowy white. Its greatest value is as a white ink for use in lithographic work.

INDUSTRY A CONSTRUCTIVE ONE

"The greatest satisfaction," says Mr. Oliver, "is that the industry will be a constructive one, instead of a destructive one as practiced in the southern pine forests of the United States. Every tree, no matter how small or how ill shapen, so long as it is healthy can be made revenue producing. It will help the lumber industry and will itself become the greatest single industry in the province."

A COMPANY ALREADY AT WORK ON CORTEZ ISLAND

A local concern has started operations in Cortez Island, at the mouth of the Campbell River, about sixty miles from Vancouver, where twenty men are employed. The men now engaged in this work are mostly ranchers residing in that locality, but it is the intention of the Vancouver company to put on about 200 workmen. The method of pursuing operations is to secure sap rights from private owners. It is estimated that a block of about 100 acres of Douglas fir gives about 800 bbl. of pitch per year, or a total of about 40,000 gal. The rancher is also provided with employment if he so desires, at \$5 a day. The majority of the landowners in the Cortez Island and adjacent districts are holding their property for the ultimate timber wealth, but the establishment of this new industry is adding much to the value of the forests.

FORTY GALLONS AT A TAPPING

The company is working on trees not less than 10 in. in diameter. Some of the larger trees are said to yield upward of 40 gal. at the first tapping. The pitch comes forth in colors varying from a bright green and deep red to a milky white. The color denotes the quality of the product, the bright green being of the highest grade. One gallon of sap produces about one-third gallon of high-grade "turps," while the residue is rich in valuable byproducts.

Forestry experts declare the Douglas fir to be the most valuable tree in the world for commercial purposes, not even excepting the rubber tree. The market is also extensive, while the price obtainable for turpentine and other resin products is four times that of pre-war days.

Nitrate Industry in Chile*

A Succinct Review of the Operation of a Nitrate Plant for the Recovery of Sodium Nitrate, Iodine and Potassium Nitrate—Needs of Improvements in This Industry and Some of the Technical Problems to Be Solved

BY ALEJANDRO BERTRAND

THE topography of the Chilean nitrate fields permits the installation of plants so that a great part of the handling of the nitrate material can be carried out by using gravity as motive force. A typical arrangement of a nitrate plant is shown in Fig.

1. The essential parts are:

1. Receiving hopper (buron).
2. Crushers (acendraderas).
3. Lixiviation tanks (cachucos).
4. Clarification tanks (chuladores).
5. Crystallization tanks (bateas).
6. Nitrate drier (cancha).

The accessories are:

7. Means of transporting the material from one stage of operation to the following.
8. High and low pressure steam generators.
9. Evaporators to concentrate the nitrate liquor and eliminate the sodium chloride.
10. Power generators.
11. Steam and liquor pipings.
12. Reservoirs for water.
13. Apparatus for the separate treatment of pulverized material or of the washed residue.
14. Machine shop.
15. Iodine house.
16. Installation for the separation of potassium nitrate.
17. Installations for getting and purifying the water needed during all the operations of the plant.

CRUSHING

The run of mine has to be transported to the plant from some distance—sometimes up to 30 km. (about 19 miles). The material is dumped directly from the cars into a receiving hopper located at the highest level of the plant. From here the material reaches the crushers, where it is reduced to 4 to 10 cm. size (1.4 to 4 in.) plus a varying amount of pulverized caliche, according to the hardness of the raw material.

Very few plants use any screening between the hoppers and crushers for a preliminary separation of the fines and of the part already of the desired size. In newly installed plants there is a tendency to use screens placed before and after the crushing operation, thus improving the hygienic conditions for the workmen and rendering more efficient the subsequent treatment of the classified material.

LIXIVIATION

The usual lixiviation tanks are open and rectangular, made of heavy sheet iron, the dimensions being 2 m. wide x 2.5 m. deep x 7 to 10 m. long (6.5 x 8 x 23 to 33 ft.) with a maximum capacity of eighty tons of material.

Each tank contains a perforated false bottom placed at 20 cm. level (about 8 in.). Low-pressure steam circulating in pipe coils serves for heating. The tanks are interconnected with siphons and provided with outlets for the liquid and means for dumping out the residues.

A 100,000-ton-per-year plant needs on the average fifty such tanks, which occupy a floor space of at least 2,000 sq.m. (21,500 sq.ft.).

The washing progresses on the counter-current principle. Generally the unscreened material from the crusher is dumped into the tanks; but in the more modern installations, when screening is used, the fines are treated separately or placed on top of the coarser materials. The complete washing of one batch of material (fondada) usually requires from 12 to 24 hr. The maximum saturation temperature of the liquid is 121 deg. C. The final washing is done with cold liquor to enable the workmen to handle the residue as soon as the liquor has been drained off.

The end of the lixiviation is usually still determined by the guesswork of the foreman. The only data which might logically indicate the actual saturation point of the wash liquor could be obtained only by chemical analysis; but the local conditions are such that analyses vary from batch to batch and therefore are of little value in actual practice. It is therefore of common occurrence to have either an incomplete washing with loss of nitrate in the residue or an excess of washing with additional heat consumption. The residue is sometimes re-treated, but usually it goes to the waste pile.

CLARIFICATION AND DECANTATION

The clarification tanks are of sheet iron, rectangular, 4 to 5 m. long x 2 to 3 m. wide x 1 to 2 m. deep (13 to 16.5 x 6.5 to 10 x 3.3 to 6.5 ft.). The bottom is inclined, the slope being 4 to 5 per cent lengthwise. The capacity of the tanks is usually sufficient to receive the saturated liquor resulting from previous 24-hr. operation.

The settling time for the liquor depends on the amount of insolubles in suspension, on the nature of these insolubles and on the temperature. All these factors vary from batch to batch, with the result that the clarification time may vary between ten minutes and many hours.

An important efficiency factor is to maintain the temperature as nearly constant as possible and at a degree which corresponds exactly to that required for the realization of a nitrate-saturated liquor. Many reagents are used to accelerate the settling of the insolubles, especially of the colloids. Among the more commonly used are: ammoniacal water, sodium carbonate, lime water, guano, manure, flour, animal glue. The action of these reagents is not yet explained in a satisfactory manner.

A symptom which is generally taken as indicating the end of the clarification period is the formation on the

*Abstract from a paper presented, Jan. 28, 1920, before the Société de Chimie Industrielle and printed in the March, 1920, issue of *Chimie et Industrie*. For the first part see *CHEM. & MET. ENG.*, April 7, 1920, pp. 655-659.

surface of a thin layer of crystals of nitrate. As soon as this takes place the liquor is decanted into the crystallization tanks.

CRYSTALLIZATION

The crystallization tanks are of heavy sheet iron 4 to 6 m. x 3.5 to 4.5 m² and about 1 m. deep (13 to 19.5 x 11.5 to 14.5 x 3.3 ft.). The bottom is inclined, the slope being 2 to 4 per cent crosswise, and is provided with two to four outlets. The total capacity of the crystallization tanks is sometimes three times but usually about twice that of the lixiviation tanks; but, due to the poorer quality of the caliche now to be treated, the tendency is to equalize the capacities of the lixiviation and crystallization tanks. The liquor is kept in the crystallization tanks for five to eight days at atmos-

water or with water saturated only with nitrate. The water dissolves the chloride and is returned to the evaporating tanks and the refined nitrate is dried and packed for shipment.

SEPARATE TREATMENT OF PULVERIZED MATERIAL

It has been mentioned above that in some plants the crushed material is screened before it is charged into the lixiviation tanks and that the powdered material is placed on top of the coarser material in the tanks or is treated separately. This last treatment is still in the experimental stage.

The pulverized material is made up into a more or less loose mud and the insolubles are separated by mechanical thickeners, by filtration, by centrifuging, or by a combination of these agencies.

FIG. 1. TYPICAL CHILEAN NITRATE PLANT

pheric temperature. Theoretically the liquor ought to contain at the maximum 400 g. nitrate per liter of solvent (at the average night temperature of 10 deg. C.) and there should be no precipitation of sodium chloride, but due to the great amount of evaporation which takes place (3 to 4 per cent of the volume) there results a concentration which sometimes passes the sodium chloride saturation limit.

There are plants where the crystallization tanks are made up to 3 m. deep where the cooling takes place with a smaller loss in evaporation, thus giving purer nitrates. The evaporation of the mother liquor ought to start only when there is no more precipitation of nitrate.

The nitrate crystals are separated from the walls and bottom and placed on inclined drain boards (falcas), whence the drained crystals are transported to be dried and packed for shipment.

During this operation care is taken to obtain only the deposition of nitrate, but this is seldom achieved, and the product is more or less contaminated with sodium chloride. This salt is separated by "refining," which consists simply of sprinkling the nitrate with fresh

The thickeners are of American make. The solids suspended in the liquid are submitted merely to a wet classification in cylindrical tanks with conical bottoms. The clarified liquid is decanted at the top and the thickened mud is evacuated at the bottom. This mud is generally passed through rotary filters and submitted to alternate suction and pressure. The rotation of the filter is slow (about one revolution per seven minutes with the Oliver type).

When no preliminary mechanical thickening is employed the filters used are of the "Butters" system. They consist of big leaves composed of a double layer of filter cloth which are immersed in the mud which is to be treated. The mud is heated somewhat and the space between the filter cloth layers is submitted to alternate vacuum and pressure. The results obtained with these filters are very encouraging.

Another method of treatment of the mud consists in the use of the "Burt" filter, which is a cylinder about 12 m. long (40 ft.) with an interior cylinder of filter cloth. The material to be treated is introduced in the inner cylinder and submitted to a pressure of 4 kg. per

sq.cm. and the cylinder is rotated at a speed of five revolutions per minute. The combination of pressure and centrifugal force accelerates the filtration. To clean the filter the pressure is applied to the outer side of the filter cloth, the rotation is increased, and the cake which is thus detached from the cloth is evacuated by the use of an Archimedean screw.

Of these methods the only one which gives highly encouraging results is the Butters method, first intro-

FIG. 2. WASHING, MECHANICAL DISTRIBUTION OF THE CALICHE

duced in 1913. By its use it has been possible to increase the efficiency of a 15 per cent caliche from 7.5 to 10 per cent and to lower the operating cost about 20 per cent.

PRODUCTION OF IODINE

The caliche contains from 200 g. to 2 kg. iodine per ton in the form of a soluble salt, which during the cycle of operations outlined above is concentrated in the final mother liquor to about 8 g. per liter; but a part of the original iodine in amounts up to 250 g. per ton is found in the commercial nitrate as sodium iodate. Although the annual total amount of iodine in the caliche treated is over 5,000 tons, the actual annual iodine production before the war reached only about 500 tons, and the maximum ever produced was 1,000 tons, in 1916.

The process now used for the subtraction of the iodine is by treating the solution of sodium iodate with sulphurous acid, with the formation of soluble sodium sulphate and a precipitation of iodine. Care must be taken not have an excess of the reagent. In practice, instead of the sulphurous acid gas, sodium bisulphite is used. Here also an excess of reagent is to be avoided, otherwise soluble iodic acid is formed and lost. The bisulphite is prepared at the plant from sodium carbonate, nitrate, carbon and sulphurous acid. The last is obtained by burning the sulphur which is found in the nitrate district.

The precipitation of iodine takes place in wooden or tin sheet tanks. An excess of reagent with the resulting loss of iodine is easily discernible by a violet color of the mother liquor.

The operations subsequent to precipitation are filtration, compression and sublimation.

POTASSIUM NITRATE

All the caliches—without exception—contain potassium nitrate from traces up to 4 per cent and some contain even as high as 10 per cent. A reasonable average would be 1 per cent.

The separation of the potassium nitrate from the sodium nitrate is accomplished by fractional crystallization. The saturation curves of these two salts cross each other at 66 deg. C. Above this temperature the potassium salt is the more soluble, but below this temperature the solubility of the potassium salt diminishes; thus at 20 deg. C. it is only a third, at zero deg. C. a sixth and at -15 deg. C. a twentieth of the solubility of that of the sodium salt. In some plants part of the potassium nitrate, amounting to 20-25 per cent of the total output, is crystallized out at the average atmospheric temperature. By a subsequent cooling to -15 deg. C. the separation of the potassium nitrate is quite complete, leaving in the final sodium nitrate only 5.5 per cent of the original total potassium salt contents.

ACCESSORY INSTALLATIONS

Some of the nitrate plants are thoroughly modern in every way and the plants of the American du Pont de Nemours Co. and of the Chilean Antofagasta Co. have introduced the most modern improvements and constitute chemical plants which might well compare with the most up-to-date chemical works to be found anywhere. The same might be said about the organization and the welfare of the employees and their families.

TECHNICAL PROGRESS IN THE CHILEAN NITRATE INDUSTRY

No substantial change in the method of working has been introduced during the last forty years, although a great many efforts are being made to find efficient improvements. More than 300 patents related to the

FIG. 3. INTERIOR OF AN EMPTY TANK

Chilean nitrate industry have been taken out in Chile on about 500 new processes and on modifications in the old ones. About 34 per cent of all these patents deal with the stage of lixiviation, some proposing to activate lixiviation by mechanical methods (rotation, agitation, etc.). Others propose preliminary classification of the raw material, to dispense with heating, to render the operation continuous, to operate in closed tanks under pressure or under a partial vacuum, to install the lixivia-

tion plants near the mines and instead of transporting the run of mine to the plant to pipe the saturated liquor to the plant, which might thus be located near the export harbors, etc. About 27 per cent of the patents refer to the different phases of the recuperation of the nitrate by evaporation and crystallization; about 10 per cent deal with a better use of the heat, and about the same amount of patents propose special methods for the treatment of pulverized caliche and of the residue. The remaining 19 per cent of the patents refer to the recovery of byproducts, such as iodine, potassium nitrate, etc.

FIG. 4. MODERN OIL-FIRED BOILER INSTALLATION

Although the patents, especially those referring to lixiviation, have not proved successful in practical application, some have led the way to partial improvements.

Among the patents which have been experimented on and which promise to become practically successful, there is one which deserves especially to be mentioned. It is that of two Chileans, Messrs. Prieto and Matus. The fundamental principle of this patent is to attach to the evaporating tank a mechanical arrangement consisting of high-speed rotating horizontal shafts provided with paddles. These paddles "skim" the surface of the liquor, the skimmed liquor is "atomized" and a strong current of hot gas carries away the moisture from the atomized products, thus effecting instantaneous "concentration."

NEED OF A TECHNICAL ORGANIZATION

The main reason, and it might be said the only reason, why the great efforts illustrated by the vast amount of patents have not been more successful is that there does not exist a technical organization commensurate with the importance of the industry, to collect the useful data of past and present experience in the industry and co-ordinate them to serve as guides for further progress. Such an organization is what is most needed at present to reduce the cost, increase the efficiency and put the Chilean nitrate industry on a technical footing which could be compared with that of the competing industry of synthetic nitrogen products.

ECONOMIC IMPORTANCE OF THE DIFFERENT STAGES OF THE NITRATE INDUSTRY

The following table shows the extreme variations in the distribution of the cost from the mine to the drier per unit of nitrate produced:

	Per Cent
Mining.....	22-35
Transportation to the plant.....	10-15
Operation at the plant.....	60-45
General expenditures.....	8-5
	100 100

If instead of figuring on the unit of nitrate the comparison is made on the basis of the caliche treated, the above figures become:

	Per Cent
Mining.....	29
Transportation to the plant.....	17
Operation at the plant.....	49
General expenditures.....	5
	100

These figures relate to pre-war costs. With the present cost of fuel the distribution of the price per unit of nitrate is about:

	Per Cent
Labor.....	42-25
Fuel.....	50-60
Water.....	5-10
Material, upkeep.....	3-5
	100-100

A summary of the cost figures in percentages showing the economic importance of each stage of the operation is as follows:

	Per Cent
Supervision.....	1 5 3
Crushing, transportation.....	6 10
Lixiviation.....	3 5
Ejection of refuse.....	6 10
Crystallization.....	1 1
Drying, etc.....	1.5-4
Fuel (total).....	50-60
Water.....	4 10
Material for repairs.....	3 6
Shop work.....	5 7

PROBLEMS TO BE CONSIDERED IN THE FUTURE CHILEAN NITRATE INDUSTRY

Reserves of Caliche. Up to now there has not been made any elaborate survey of the nitrate zone. The following figures give what according to reliable authorities might be considered as being the total workable raw nitrate in the Chilean nitrate fields with the percentages of caliche:

Millions of Tons of Raw Nitrate	Percentages of Caliche
9	45-38
18	38-32
32	32-25
51	25-18
80	18-10
130	10-8
320	

These figures would indicate that at the pre-war rate of consumption the reserve is sufficient to provide for the world's consumption for more than 100 years.

FIG. 5. CRYSTALLIZING TANKS

Water. At present from 200 to 300 l. of water are required per metric quintal of nitrate, which indicates that from 10,000,000 to 12,000,000 tons of water is needed annually to supply the nitrate industry. This amount is amply available from the Rio Loa and

especially from the underground waters which according to the exploration results are abundant in the region. But the technical problem to be solved is the purification of this underground water, because it contains 0.1 to 0.3 per cent and even as high as 1 per cent of sodium chloride besides chlorides and carbonates of magnesium and calcium, which are scale producers and very harmful to the life of the boilers and evaporators.

Fuel. The present annual consumption of fuel, including that required by the railways of the region, amounts to more than 300,000 tons of coal and 800,000 tons of oil, all of which have to be imported. A point which requires special study is that although theoret-

FIG. 6. GENERAL VIEW OF DRIERS

ically only about 200 calories would be required for the recovery of 1 kg. of nitrate, in reality more than 1,100 calories are used now per kg. of nitrate.

Steam and Mechanical Energy. The more economical production of high pressure steam (source of energy) and of low pressure steam (source of heat), the substitution of heating by gas, the utilization of the Rio Loa hydraulic power (4 cu.m. per sec. with a head of over 1,500 m.) constitute as many problems to be solved.

With a caliche of 18 per cent nitrate, the consumption of energy is 1 kw.-yr. per 1,000 tons of nitrate.

The uses of the energy may be classified as follows:

	Per Cc
Crushing, transportatic	70
Circulation of liquids..	15
Shops	5
Light	10

Until a few years ago every plant had its own electric power house. Now there are a few central stations supplying the needs of the region. Much remains to be done in the erection of hydro-electric or thermo-electric central stations.

Substitution of Mechanical Power for Hand Labor. The substitution of mechanical power for hand labor has not shown any economical improvement, although a laborer who was paid 3 f. (about 60c.) per day in 1900 and about 6 f. (about \$1.20) per day in war time gets even more now, but it may be expected that in the near future mechanical appliances instead of manual labor will find wider uses in the Chilean nitrate industry.

Other Problems. Among the other problems to be considered are: Preliminary treatment at the mine, lowering the percentage of waste, efficient evaporation in the air, making the fractional crystallization and drying operations rapid, automatic and continuous, better uses of gravity railways, shipment of nitrate in blocks or briquets instead of in sacks.

Durability of Electric Heaters for Gasoline Distillation*

By W. A. JACOBS† AND E. W. DEAN‡

THE petroleum division of the Bureau of Mines, in its laboratory investigations, has had occasion to develop a number of types of electrical heating equipment. It was found that electric heaters could be used to particular advantage in the standard distillation test for gasoline.¹ In order to assist in rendering this type of heater available for general use, a description of the apparatus developed by the Bureau was published.² Shortly after the article was printed a chemical supply house undertook the manufacture of an electric heater suitable for gasoline distillation. A preliminary model was examined and tested by the Bureau and modifications were suggested that were incorporated in the type of heater that was finally marketed.

The electric heater developed by the Bureau has an inverted conical resistance element surrounded by a layer of heat-insulating material and mounted in a metal case having a top of hard asbestos (Transite) board. The resistance element is a helix of nickel-chromium alloy wire held by a molded core of alundum. The Bureau heaters are generally of about 330 watts capacity and are used with stock types of regulating rheostats capable of reducing the effective wattage to about one third the full-load maximum.

The commercial heater has a helix of nickel-chromium alloy wire resting in a spiral groove cut in a depression in a block of heat-insulating composition. The coils of wire are held in place by a special cross of sheet mica. The combination of resistance element and heat-insulating layer is mounted in a metal case which also incloses a regulating rheostat. The full-load capacity of this heater is about 260 watts.

COMPARISON OF THE BUREAU OF MINES TYPE AND COMMERCIAL TYPE OF HEATERS

Both types of heaters have been used in the Bureau laboratories, and are capable of doing about the same work. The lower apparent capacity of the commercial heater is compensated for by its greater thermal efficiency, which is due to the detail of construction involving coils held lightly by grooves in a block of heat-insulating material. The commercial heater was somewhat more satisfactory to use, because of its more rapid response to changes in current, as controlled by the rheostat, and because of the latter's convenient location.

Tests have been made to determine the life of the two types of heaters, each operated at full-load capacity. The results were briefly as follows:

Commercial heater:	Amp.
Initial current consumption with 110-volt alternating current.....	2.3
Current consumption, end of 500 hr. running..	2.1
Burned out after exactly 500 hr., apparently because the insulating block had disintegrated so that the coils of wire short-circuited.	
Bureau of Mines heater:	
Initial current consumption with 110-volt alternating current.....	3.0
Current consumption at end of 500 hr.....	2.4
Burned out at end of 505 hr., apparently because one small length of wire overheated.	

*Reports of Investigations, U. S. Bureau of Mines.

†Assistant Chemist, Bureau of Mines.

‡Organic Chemist, Bureau of Mines.

¹Dean, E. W., "Motor Gasoline, Properties, Laboratory Methods of Testing and Practical Specifications," Bureau of Mines Technical Paper 214, 1919, 33 pp.)

²Dean, E. W., "A Convenient Electric Heater for Use in the Analytical Distillation of Gasoline," *J. Ind. Eng. Chem.*, vol. 10, 1918, p. 823.)

These results indicate that under conditions of the test the two heaters were practically equal in durability. The commercial heater failed evidently from deterioration of the insulating block, whereas the Bureau of Mines heater failed from destruction of the resistance wire at one spot, where overheating may have occurred or where the wire may have been defective. The slow deterioration of wire in the commercial heater, which is also indicated by a smaller falling off in current consumption, was to have been expected on account of the lighter load it had to carry.

In actual service, the commercial heater probably would have burned out in a relatively shorter time than under test conditions because disintegration of the insulating block would have been accelerated by movement and jarring. The Bureau heater, on the other hand, failed through destruction of the wire, which would not have been accelerated by movement.

SUMMARY

A Bureau of Mines electric gasoline distillation heater and a commercial device sold for the same use were subjected to life tests at maximum current load. Each failed at the end of approximately 500 hr., the Bureau heater through deterioration of the resistance wire, and the commercial heater through disintegration of the block of insulating material holding the resistance wire.

The commercial heater probably would have failed in actual service in somewhat less time than the Bureau heater.

The life of either heating element would not necessarily be the same in actual service as under the conditions of the test described, but is sufficiently great to render the cost of replacements a negligible part of the expense of making distillation tests on gasoline.

Air Lift Pumping

The wide application of the air lift pumping principle to the handling of acids and chemical solutions as well as of water from deep wells promotes a constant interest in anything regarding this system of pumping.

At the Chemical Industries Exposition in New York next month, the Sullivan Machinery Co. will show an operating model of its air lift system, illustrated by the accompanying cut.

This model is operated by a small, vertical, air-cooled air compressor, belt driven by a $\frac{1}{2}$ -hp. electric motor. In this model the well or other source of supply is represented by the vertical copper chamber 1. Water flows by gravity from this through the pipe at the bottom of the model, over to the riser 3, which is made of glass to show the operation of the lift. Air is introduced into this riser or eduction pipe at the base through the Sullivan footpiece or pump 2, which is a taper brass fitting with numerous holes, to permit the discharge of the water upward. In handling acid or other chemicals this part is made of resistant material such as cast iron, cast steel, hard rubber or lead. The water in the eduction pipe, being aerated by the introduction of air, rises in the tube into the chamber 4, which is a model Cyclone Booster made of glass. The air is given a swirling motion by the introduction of water at a tangent to the circumference of the chamber; this has the effect of separating the air from the water.

A certain portion of the air is permitted to escape through a vent valve, the remainder exerting a back pressure on the water in the Booster chamber and forcing

MODEL OF AIR LIFT PUMPING

ing it along the horizontal discharge line 5. Frequently in actual practice discharge above the surface is desired. The Booster is able to handle work of this sort, using the same air which raised the water or acid from the pump or well. To assist this action, particularly in cases of high discharge, an auxiliary jet or re-lift jet 6 is frequently used. In this case a portion of the air from the Booster is carried in a pipe parallel to the discharge line, as shown in the model, and introduced into the riser by means of a small pump or foot-piece, which is also shown. The tank 7 represents the storing station or collecting tank, from which the water or acid is handled by gravity or other pump to its final destination.

Dominion Oxygen Co., Ltd., Completes Initial Plant

The sensational development of Canadian industries in pre-war days was a weak and toddling growth compared to the mighty strides the Dominion is making industrially today. From 1905 to 1915 the capital invested in Canadian factories increased more than 135 per cent and the value of factory products advanced roughly from \$700,000,000 to \$1,400,000,000. It would be rash to attempt an estimate of Canada's industrial growth since 1915, but it is not a guess to assert that the Dominion has forged ahead industrially as never before in its history.

One of the most important recent announcements bearing on Canada's future industrial development is that of the Dominion Oxygen Co., Ltd.'s, promised erection of a chain of great oxygen plants for separating oxygen from the atmosphere. These plants will be situated in five of the Dominion's industrial centers, and service stations will be established throughout Canada to supply oxygen users wherever there is a demand for the gas, either on or off the railroad.

The first of these plants has already been completed at Toronto, and it is said to be the largest oxygen plant ever built in Canada. It will supply the Canadian market through an extensive warehousing system, pending the erection of the additional plants. The sites for these additional plants have been secured at Montreal, Winnipeg and other points, so that the work of construction may be prosecuted as rapidly as possible.

A Laboratory High-Temperature Coke-Resistance Electric Furnace

BY W. FAITOUTE MUNN

FROM time to time variously constructed furnaces heated by means of an electric current are required for laboratory research. Most of them are heated by wrapping a layer of wire, of high melting point, around the refractory substance and then passing the current through the resistor until the desired temperature is obtained. It is obvious that the maximum temperature from such a furnace depends chiefly upon two things—namely, the melting point of the wire used as the heating element and the nature and the melting point of the refractory substance with which the wire is in contact. The result is that temperatures often desired in the experimental laboratory cannot be obtained by this means or type of furnace. As the setting up of the larger and greater capacity electric furnaces usually requires special wiring and considerable expense, the work is generally abandoned and perhaps an excellent idea is set aside.

For temperatures up to 1,500 deg. C. there is not much difficulty in obtaining or making a laboratory electric furnace. For temperatures of 1,800 deg. C. and higher not much information has been given as to the construction of a furnace on a laboratory scale which will not only be inexpensive to make and to operate but also be easily raised to the maximum temperature in a minimum of time.

S. A. Tucker¹ has described a granular carbon-resistance furnace designed for 30 to 35 kw. which in general is similar to the one about to be described, but which would not be convenient for a small laboratory. The voltage, controlled by means of varying the field winding of the alternator, is excellent if the energy is produced in the immediate vicinity of the furnace, but if this is not possible, the alternative, using an auto transformer or an impedance coil for resistance, adds to the bulk of equipment and to the cost of installation.

The Borchers furnace² also probably belongs to this class of furnace, but instead of being heated by means of coke particles, the temperature is obtained by passing the current through a small carbon rod connecting the graphite electrodes. This arrangement would not be the proper one for heating substances in crucibles.

A convenient laboratory electric furnace for temperature up to 2,300 deg. C. is that of the granular coke-resistance type using 1-in. graphite electrodes and a 1½-in. graphite crucible.³ The rods, which are supported by suitable sized pipe-fittings, pass through Silocel brick and continue to within about 1½ in. of the

crucible. Granulated coke is used to fill the space around the graphite electrodes and crucible. The graphite crucible is made by sawing off a length of graphite rod of desired diameter and drilling out the center by means of a lathe or with a wood bit of 1-in. diameter by hand. The entire furnace is constructed of 9 x 4½ x 2½ in. Silocel blocks.
